Enthalpy of Formation

We calculated $\Delta_f H°$(MgF, g, 298.15 K) = −56.6 ± 2.0 kcal·mol^{-1} from an adopted. $\Delta_{at} H°$(MgF, 298.15 K) = 110.7 ± 2 kcal·mol^{-1} which is derived from a 3rd law analysis of three sets of mass spectral–equilibrium data reported by Murad *et al.*[1] and Hildenbrand.[2] Also included in the analysis are independent mass spectrometer–equilibrium measurements on MgF(g) by Ehlert.[3,4]

Reactions: (A) Tl(g) + MgF(g) = TiF(g) + Mg(g) (B) Mg(g) + MgF_2(g) = 2 MgF(g) (C) AlF_3(g) + 2 Mg(g) = AlF(g) + 2 MgF(g)
(D) 2 MgF(g) = Mg(g) + MgF_2(cr)

[a]One point rejected due to failure of a statistical test.

[b]Free–energy functions (FEF) for TiF(g) are calculated from spectral data;[5] FEF for Tl(g) are from Hultgren.[6]

[c]3rd law Values; all auxillary $\Delta_f H°$(298.15 K) from JANAF Thermochemical Table[8] except for Tl and TlF.[7]

We dismiss the measurements of Ehlert[3] and Ehlert *et al.*[4] since our analyses show that their equilibrium data most likely contain temperature dependent errors. Furthermore, their results[3,4] yield $D_0°$ values which are less than that predicted by the Rittner ionic model. Krasnov and Karaseva[9] have applied this potential function to all the alkaline earth monohalides and found that it establishes a lower limit for $D_0°$. Recalculation of their results[9] sets $\Delta_{at} H°$(MgF, 298.15 K) > 110.4 kcal·mol^{-1}. Application of this ionic model to MgF is justified since the spin densities calculated from the ESR spectra[10] of matrix–isolated MgF show that the molecule is indeed highly ionic.

Trends in the well–established values of the ratio $\Delta_{at} H°(MX, 298.15\ K)/\Delta_{at} H°(MX_2, 298.15\ K)$ for the majority of the alkaline earth halides[8] suggests a value for MgF/MgF_2 which is less than or equal to 0.45. This sets the upper limit of $\Delta_{at} H°$(MgF, 298.15 K) at 111 kcal·mol^{-1} when $\Delta_{at} H°$(MgF_2, 298.15 K) = 246.7 kcal·mol^{-1}.[8] If MgF_2(g) is linear then the maximum $\Delta_{at} H°$(298.15 K) value increases to 112.6 kcal·mol^{-1} suggesting a possible uncertainty in the adopted $D_0°$ of ±2 kcal·mol^{-1}. Our adopted results give $\Delta_{at} H°$(MgF, 298.15 K)/Δ_{at}H(MgF_2, 298.15 K) = 0.44_9.

Our selected thermochemical $\Delta_{at} H°$(298.15 K) value converted to 0 K is 4.76 eV (109.8 kcal·mol^{-1}). Other values for $D_0°$ which were considered but believed less reliable are (all in ev 4.0,[11] 5.0 or 4.7[11] and 4.2.[12] These spectroscopic values have been derived from linear Birge–Sponer extrapolations of the ground state ($X^2\Sigma^+$) and first excited state ($^2\pi$) vibrational levels. We obtain $D_0° = 3.2_2$ eV from a linear Birge–Sponer extrapolation with our adopted ground state vibrational constants. This value adjusts to 3.59 eV when corrected for the ionicity[2] of the Mg–F bond. The corrected $D_0°$ value is 1.2 eV less than the thermochemical result. This discrepancy is most likely due to the use of an inaccurate value for the anharmonic constant, $\omega_e x_e$, in the Birge–Sponer extrapolation. The use of lower reported values[12,15] for $\omega_e x_e$ brings the spectroscopic and thermochemical $D_0°$ values into much better agreement but leaves the thermodynamic functions for MgF unaltered. In addition, Singh *et al.*[10] have employed a method to fit an electronegative potential energy function to the expermimental potential energy curves which yields $D_0° = 4.45$ eV. This value agrees with our results within probable error limits.

Heat Capacity and Entropy

The electronic levels and vibrational–rotational constants are taken from the compilation of Rosen.[5] Values of these constants, tabulated for $Mg^{24}F$, are corrected for the natural isotopic abundances of magnesium. The value of α_e listed by Rosen for the $C^2\Sigma^+$ state is incorrect. The rotational constants are based on an analysis[14] of the rotational structure in the bands of the A–X, B–X, and C–X systems. Barrow and Beale[14] used the Pekeris relation[12] to calculate $\omega_e x_e$ values from their spectroscopic α_e's. These $\omega_e x_e$ values were combined with $\Delta G_{1/2}$ values to give ω_e. These estimates of ω_e and $\omega_e x_e$ differ somewhat from those obtained from a vibrational analysis[15] of band head measurements.

Enthalpy of Formation

MgF^+ ionization–efficiency curves obtained from mass spectral observations on the MgF_2[1] and MgF_2–Al[2] systems are of the two–process type. Evidence[1,2] has been presented which shows that the low–energy portion (<13 eV) of the curve arises from the direct ionization (A) of MgF(g). These curves also show an inflection point at higher energies (~14 eV) which has been interpreted[1-3] as due to the onset of the dissociative ionization (B) of MgF_2(g). The appearance potentials, in eV, which have been observed for these two processes from measurements on various MgF_2 systems are tabulated below.

Source	Year	System	(A) Direct Ionization	(B) Dissociative Ionization
Berkowitz and Marquart[4]	1962	MgF_2		13.5±0.4
Green *et al.*[1]	1964	MgF_2		13.6±0.3
Ehlert *et al.*[2]	1964	MgF_2–Al	7.8±0.3	13.7±0.4
Murad *et al.*[5]	1966	MgF_2–Tl–Pd	8.0±0.5	
Hildenbrand[6]	1968	MgF_2–Cu	7.5±0.3	
Hildenbrand[3]	1968	MgF_2	7.5±0.5	

(A) $MgF(g) + e^- \rightarrow MgF^+(g) + 2\ e^-$ (B) $MgF_2(g) + e^- \rightarrow MgF^+(g) + F(g) + 2\ e^-$

Both sets of data show the normal scatter (0.5 eV) expected for such measurements. The mean value (7.7 ± 0.4 eV) of the four AP's for the direct ionization (A) is supported by the spectroscopic ionization potential of 7.68 eV.[7] We adopt $\Delta_f H° = 177.56 \pm 9\ kcal·mol^{-1}$ (7.7 eV) for process (A), and we obtain $\Delta_f H°(MgF,^+ g) = 121.1 \pm 11.0\ kcal·mol^{-1}$ when the $\Delta_r H°$ value is combined with $\Delta_f H°(MgF, g) = -56.5 \pm 2.0\ kcal·mol.^{-1}$[8] The fragmentation process (B) is likely to involve unknown kinetic energy factors and would not be expected to yield as reliable $\Delta_f H°$ value as obtained from direct ionization. However, the mean value (13.58 ± 0.5 eV) of the four AP's for process (B) leads to $\Delta_f H°(MgF^+, g, 0\ K) = 121.5 \pm 13.0\ kcal·mol^{-1}$ which is in remarkably good with the $\Delta_f H°$ value from direct ionization (121.1 $kcal·mol^{-1}$). This implies that the excess kinetic energy of the fragment MgF^+ is small.

Heat Capacity and Entropy

The bond dissociation energy for MgF^+ (108.6 $kcal·mol^{-1}$) is nearly the same as that for MgF(109.8 $kcal·mol^{-1}$)[8] which implies that the bonding in these two molecules is quite similar. Thus, it is reasonable to assume that $r_e(MgF^+) = r_e(MgF)$. We adopt the measured r_e value (1.75 Å) for MgF.[8] B_e is calculated from the adopted value for r_e. The value of ω_e is obtained from Badger's rule[9] which is written in the form $\omega_e^2 = 3.159 \times 10^6/\mu$ ($r_e = d_{ij}$).[3] Molecular data[8] for NaF, MgF, and MgO are used to determine the constant d_{ij}. Barrow and Caunt[10] have shown that the product $x_e^{1/2}$ is fairly constant within a group of similar molecules. We assume $x_e(MgF^+) = x_e(MgF)$ since $^1/_2(MgF^+) = {}^1/_2(MgF)$. These estimates of ω_e and $\omega_e x_e$ are only slightly different from those observed for MgF.[8] α_e is obtained from the other constants assuming a Morse potential function.

Novikov and Gurvich[11] have observed a band system in the emission spectrum of MgF near 54000 cm^{-1}. An analysis of the vibrational structure showed that the system did not belong to any of those known for MgF, and they[11] assigned it to the $^1\Sigma$–$^1\Sigma$ transition of MgF^+. Band systems have appeared in the absorption spectra[12,13] of MgF which are now known to arise from AlF. A comparison of the vibrational constants reported by Novikov and Gurvich[11] with those for AlF[8] strongly suggests that this system is the $B^1\Sigma$–$X^1\Sigma$ transition of AlF. Barrow[14] has come to the same conclusion.

MgF^+ (8 valence elecrons) is isoelectronic with the alkaline earth monoxides. We estimate the electronic states and levels for MgF^+ by analogy with those for these isoelectronic molecules,[8] particularly MgO. The $^1\pi^{-3}\pi$ splitting of MgO has recently been reported as 900 ± 200 $cm.^{-1}$.[15] We believe that our adopted electronic entropies represent minimal values. Probable upper limits for the electronic contributions can be established by decreasing the two lowest triplet levels to 1000 cm^{-1} ($^3\pi$) and 5000 cm^{-1} ($^3\Sigma$) and neglecting the other excited states. This increases the entropy to 65.1 and 78.6 cal $K^{-1}·mol^{-1}$ at 1000 K and 4000 K, respectively. The enthalpy is much more uncertain, approaching ±3.0 $kcal·mol^{-1}$ at temperatures in excess of 2000 K.

Enthalpy of Formation

The adopted enthalpy of formation at 298.15 K is that derived by Brewer[1] from the high temperature mass spectrometric measurements of equilibria among gaseous molybdenum fluorides by Hildenbrand [2054–2242 K].[2] The value of $\Delta_f H°$(0 K) combined with JANAF data[3] for Mo(g) and F(g) gives D_0°(MoF) = 107.9±4 kcal·mol^{-1}.

Heat Capacity and Entropy

We use the ground state vibrational frequency of 700 cm^{-1} estimated by Hildenbrand[2] and adopted by Brewer.[1] The Mo–F bond distance, 1.82 Å, is the Mo–F bond distance in MoF_6(g) used by Brewer.[1] The electronic contributions are assumed to be the same as those for the free gaseous Mo^+ ion, as suggested by Brewer.[1] All states up to 17344 cm^{-1} as listed by Moore[4] are included in the calculation. Our thermodynamic functions differ slightly from those reported by Brewer[1] because of the use of non zero values for $\omega_e x_e$ and α_e. The estimates for $\omega_e x_e$ and α_e are based on the empirical correlations of Calder and Ruedenberg.[5]

This table is based on the critical analysis of data existing in 1978 by Brewer.[1]

Enthalpy of Formation

The enthalpy of formation is obtained by taking an average of two estimates of the dissociation energy of NF. The first estimate of 3.15 eV (72.4 kcal·mol^{-1}) was obtained from Price *et al.*[1] The second estimate of 70.4 kcal·mol^{-1} is obtained by taking one half the dissociation energy of NF_2(g) calculated from JANAF values. The $\Delta_f H°$(298.15 K) for NF(g) was then calculated with auxiliary JANAF data from a dissociation energy of 71.4 kcal·mol^{-1}.

Heat Capacity and Entropy

The ω_e value was obtained from infrared studies of Milligan and Jacox.[2] The r_e value was estimated from Guggenheimer's[3] relation for single bonded molecules. The anharmonicity constant x_e is estimated by assuming the separation of the vibrational levels to be a linear function of the vibrational quantum number. The α_e value is then calculated using the Morse potential function; B_e is determined from the bond length. The ground state configuration is assumed to be the same as that in NBr.

Point Group: C_s

Bond Distances: N–O = 1.13 Å; N–F = 1.52 Å

Bond Angle: O–N–F = 110.2°

Product of the Moments of Inertia: $I_A I_B I_C = 49.6113 \times 10^{-117}\ g^3·cm^6$

Enthalpy of Formation

For the reaction $2NO(g) + F_2(g) \rightarrow 2ONF(g)$, Johnston and Bertin[1] report $\Delta_f H°(298.15\ K) = 74.8 \pm 0.8\ kcal·mol^{-1}$, determined calorimetrically. This yields $15.7 \pm 0.4\ kcal·mol^{-1}$ for $\Delta_f H°(298.15\ K)$.

Heat Capacity and Entropy

Stephenson and Jones,[2] report the frequencies, obtained from the infrared spectrum, and moments of inertia, obtained from the microwave spectrum. The principal moments of inertia are: $I_A = 0.8778 \times 10^{-39}$, $I_B = 7.0919 \times 10^{-39}$, and $I_C = 7.9697 \times 10^{-39}\ g·cm^2$.

Ground State Quantum Weight: 1 $\sigma = 2$
Point Group: C_{2v}
Bond Distances: N–F = 1.40 Å; N–O = 1.21 Å
Bond Angles: O–N–O = 129.5°; F–N–O = 115.25°
Product of the Moments of Inertia: $I_A I_B I_C = 6.400639 \times 10^{-115}\ g^3·cm^6$

Enthalpy of Formation

The enthalpy of reaction at 25°C for direct synthesis of nitryl fluoride from nitrogen dioxide with fluorine ($NO_2(g) + 1/2\ F_2(g) = NO_2F(g)$) has been measured calorimetrically as $-33.9\ kcal·mol^{-1}$ by Breazeale and MacLaren.[1] The enthalpy of formation, $\Delta_f H°(298.15\ K) = -26.0\ kcal·mol^{-1}$, for $NO_2F(g)$ was then drived. The values of $\Delta_f H°(298.15\ K) = -20 \pm 5$ and $-19 \pm 2\ kcal·mol^{-1}$ were issued in their second and third quarterly technical reports and have been quoted in the literature by Tschuikow-Roux.[2]

Hetherington and Robinson[3] quoted $\Delta_f H° = 26\ kcal·mol^{-1}$ (presumably it has a minus sign) for $NO_2F(g)$ which was derived from the heat of solution measured by Nichols and Robinson.[4]

Heat Capacity and Entropy

Smith and Magnuson[5] have measured the moments of inertia from microwave spectrum of $NO_2F(g)$. In order to calculate the bond distances, given as N–F = 1.35 Å and N–O = 1.23 Å, the bond angle O–N–O was assumed to be 125°. The selected bond distances and angle were obtained from Clayton *et al.*[6] Clayton *et al.* assumed the bond angle O–N–O in $NO_2F(g)$ should be the same as that in $NO_2Cl(g)$ and then calculated the bond distances N–F and N–O from Smith and Magnuson[5] data of the moments of inertia.

The selected vibrational frequencies were obtained from the infrared and Raman spectra measurements by Dodd *et al.*[7]

The three principal moments of inertia are: $I_A = 6.3641 \times 10^{-39}$, $I_B = 7.3394 \times 10^{-39}$, and $I_C = 13.7034 \times 10^{-39}\ g·cm^2$.

Ground State Quantum Weight: [1] $\sigma = 1$

Point Group: C_s

Bond Distances: O–N = 1.29 ± 0.05 Å; N–O' = 1.39 ± 0.05 Å; O'–F = 1.42 ± 0.05 Å

Bond Angles: O–N–O = 125° ± 5°; F–O'–N = 105° ± 5°

Angle between NO'F plane and O_2NO' plane = 90°

Product of the Moments of Inertia: $I_A I_B I_C = 3.88611 \times 10^{-114}\ g^3·cm^6$

Enthalpy of Formation

The value, 2.5 ± 0.5 kcal·mol^{-1}, for the enthalpy of formation of FNO_3(g) was obtained from Anderson, *et al.*[1] The value of $\Delta_f H°$ reported by Talakin, *et al.*[2] was 4.2 ± 0.9 kcal·mol^{-1} at 294 K.

Heat Capacity and Entropy

Vibrational frequencies were estimated by comparison with those of HNO_3(g) reported by Palm and Kilpatrick.[3] Bond distances and angles were taken from Pauling and Brockway.[4] The three principal moments of inertia are: $I_A = 8.8638 \times 10^{-39}$, $I_B = 18.5651 \times 10^{-39}$, and $I_C = 23.6154 \times 10^{-39}\ g·cm^2$. The possible existence of restricted internal rotation in the molecule was not considered. Thus the calculated values of $C_p°$ and $S°$ may be low.

Fluorine Nitrate ($FONO_2$) $F_1N_1O_3$(g)

$S°(298.15\ K) = 51.212 \pm 0.08\ J·K^{-1}·mol^{-1}$
$T_{fus} = 1269 \pm 2\ K$

$\Delta_f H°(0\ K) = -573.013 \pm 0.8\ kJ·mol^{-1}$
$\Delta_f H°(298.15\ K) = -575.384 \pm 0.8\ kJ·mol^{-1}$
$\Delta_{fus} H° = 33.346\ kJ·mol^{-1}$

Enthalpy of Formation

The enthalpies of solution and reaction of NaF(cr) have been determined by many investigators. Incorporating their reported data with auxiliary $\Delta_f H°$(298.15 K) values,[1,2] we calculate the corresponding values of $\Delta_f H°$(NaF, cr, 298.15 K). The results are presented in the table below. The adopted $\Delta_f H°$(NaF, cr, 298.15 K) is $-137.52 \pm 0.2\ kcal·mol^{-1}$ ($-575.384 \pm 0.8\ kJ·mol^{-1}$).

Source	Reaction*	T/K	Concentration NaF·nH$_2$O	No. of Determination	$\Delta r H°$(298.15 K) kcal·mol^{-1}	$\Delta_f H°$(298.15 K) kcal·mol^{-1}
Guntz (1884)[1]	A	285	400	1	0.13	−137.42
Latimer–Jolly (1953)[2]	A	298	1850	2	0.23±0.01	−137.52
Hepler *et al.* (1953)[3]	A	298	1540	1	0.22±0.01	−137.51
Davies–Benson (1965)[4]	A	298	222	1	0.24±0.01	−137.53
Thomsen (1882)[5]	B	291		2	16.24±0.15	−137.38
Wartenberg–Fitzner (1926)[6]	C	293	—	1	−39.3 ±0.1	−137.62
Schmitz–Schumaker (1947)[7]	C	291	—	1	−39.5	−137.82
Coughlin (1958)[8]	D	298		6	−1.40±0.06	−137.58
Vorob'yev–Skuratov (1960)[9]	E	298	—	5	−325.5 ±2.2	−137.13

*Reaction A) NaF(cr) = NaF(n H_2O) and $\Delta_r H°(298.15\ K) = \Delta_{sol} H°$; B) NaOH($H_2O$, 200 K) + HF($H_2O$, 200 K) + H_2O(NaF401 H_2O);
C) NaCl(cr) + 1/2 F_2(g) = NaF(cr) + 1/2 Cl_2(g); D) NaCl(cr) + HF(H_2O, 5.716 K) = NaF(cr) + HCl(H_2O, 2.731K);
E) 4 Na(cr) + CF_4(g) = 4 NaF(cr) + C (graphite).

Heat Capacity and Entropy

The low temperature heat capacities, 0.05–15 K and 54.01 –295.86 K, were measured by Harrison *et al.*[10] and King,[11] respectively. These two sets of data are joined smoothly with the high temperature heat capacities at 298 K which were derived from the enthalpy measurements, 406.1–1282.2 K, determined by O'Brien and Kelley.[12] The $C_p°$ values above 1282.2 K are obtained by linear extrapolation. $S°$(298.15 K) is calculated using the adopted low temperature heat capacities and $S°(54\ K) = 0.555\ cal\ K^{-1}·mol^{-1}$.

Frank[13] commented that the temperature measurements of O'Brien and Kelley[12] seemed to be about 20 K high at 1000 with a smaller error at lower temperatures. A correction for the assumed error in the temperature measurement was used in the previous JANAF table. However, Douglas and Ditmars[14] have questioned this correction, since new enthalpy data for AlF_3 yielded $C_p°$ values in better agreement with the original $C_p°$ values of O'Brien and Kelley than with the corrected values of Frank. The $\alpha \rightarrow \beta$ transition of AlF_3(cr) was found in the range 723–6 K, while O'Brien and Kelley selected 727 K based on a point at 728.1 K in the β region and a point at 724.9 K in the pretransition region. Frank's correction yields an error of 9 at 727 K, yet the true error appears to be negligible (≤2) for AlF_3(cr). Based on the above reasoning and the comparison of the $C_p°$ curve of NaF(cr) with those of NaCl(cr), LiCl(cr) and LiF(cr) in the temperature range 300–1300 K, we adopt the high temperature enthalpy data of O'Brien and Kelley without any correction.

The low temperature heat capacities in the temperature ranges 81–190 and 198–273 K were also measured by Koref;[15] and high temperature enthalpies at temperatures 288–1073 and 290–1287 K were reported by Krestovnikov and Karetnikov,[16] and Lyashenko,[17] respectively. They are not used for evaluation.

Fusion Data

Refer to the liquid table for details.

Sublimation Data

$\Delta_{sub} H°(298.15\ K) = 284.93\ kJ·mol^{-1}$ is calculated as the difference between $\Delta_f H°$(298.15 K) for NaF(g) and NaF(cr).

Sodium Fluoride (NaF) LIQUID M_r = 41.988173 Sodium Fluoride (NaF) $F_1Na_1(l)$

$S°(298.15\ K)$ = [73.464] $J·K^{-1}·mol^{-1}$
T_{fus} = 1269 ± 2 K

$\Delta_f H°(298.15\ K)$ = [−546.204] $kJ·mol^{-1}$
$\Delta_{fus}H°$ = 33.346 $kJ·mol^{-1}$

Enthalpy of Formation

$\Delta_f H°(NaF_3,l, 298.15\ K)$ is calculated from $\Delta_f H°$(NaF, cr, 298.15 K) by adding the enthalpy of fusion, $\Delta_{fus}H°$, and the difference in enthalpy, $H°(1269\ K)–H°(298.15\ K)$, between the crystal and liquid.

Heat Capacity and Entropy

The heat capacities of NaF(l) are derived from the enthalpy data, 1287.6–1746.5 K, determined by O'Brien and Kelley.[1] A glass transition temperature is assumed at 900 K. The heat capacities below 900 K are taken from those for NaF(cr). The $C_p°$ values above 1746.5 K are obtained by extrapolation. The entropy is calculated in a manner analogous to that used for the enthalpy formation.

Fusion Data

The value of T_{fus} has been reported as (K): 1313,[2] 1285,[1] 1270,[3,4,5] 1269,[6] 1268,[7,8,9] 1267,[10,11,12] 1265,[13] 1263,[14] and 1253.[15] We select T_{fus} = 1269 K. The value 1285 K reported by O'Brien and Kelley seems unreasonably high and is not adopted. The cause of this discrepancy is still unresolved.[17] The heat of melting is calculated as the difference between the adopted enthalpies for NaF(cr) and NaF(l) at 1269 K. Kelley[18] derived $\Delta_{fus}H°(1265\ K)$ to be 5.82 8.43 $kcal·mol^{-1}$, based on 13 sets of molten salts equilibrium data involving NaF. The value $\Delta_{fus}H°(1285\ K)$ = 8.03 $kcal·mol^{-1}$ reported by O'Brien and Kelley is not used.

Vaporization Data

T_{vap} = 2060 K is the temperature at which the partial pressures of NaF(g) and Na_2F_2(g) in equilibrium with NaF(l) equal one atmosphere. The vapor composition at T_{vap} is evaluated as NaF 84.8% and Na_2F_2 15.2%. The heat required to vaporize one mole of liquid to form 0.868 mole of vapor mixture of the above composition at T_{vap} is calculated to be 42.1 $kcal·mol^{-1}$ (176.146 $kJ·mol^{-1}$).

Ruff *et al.*[16] measured the vapor pressure of NaF(l) in the temperature range of 1699–1974 K and reported T_{vap} = 1978 K.

Enthalpy of Formation

The total pressure of NaF(g) and Na_2F_2(g), in equilibrium with NaF(cr,l) at temperatures 1020–1974 K, have been determined by many investigators, using manometric,[1, 2, 5] torsion–effusion,[6, 8] Knudsen effusion,[3, 7] transpiration,[4] and molecular–beam velocity–selector[9, 10] methods. In order to evaluate $\Delta_{vap}H°$(LiF, g) we have used a trial and error variation of $\Delta_{sub}H°$ and $\Delta_{vap}H°$ for the monomer and dimer such that the $\Delta_f H°$(298.15 K) values derived by the 2nd and 3rd law methods are in reasonable agreement.

Incorporating $\Delta_{sub}H°(298.15\ K) = 68.1$ and 72.7, and $\Delta_{vap}H°(298.15\ K) = 61.12$ and 58.75 kcal·mol^{-1} for NaF and Na_2F_2, respectively, with JANAF functions for NaF(cr), NaF(l), NaF(g) and Na_2F_2(g), we derive the partial pressures of NaF monomer from the reported total pressures. Based on the calculated partial pressures of NaF(g), the corresponding enthalpy of vaporization are evaluated by the 2nd and 3rd law methods. Using the 3rd law $\Delta_f H°(298.15\ K)$ and $\Delta_f H°(298.15\ K) = -137.52$ and -130.545 kcal·mol^{-1}for NaF(cr) and NaF(l), we obtain values of $\Delta_f H°$(298.15 K) for NaF(g). The results are presented in the table below. The $\Delta_f H°$(NaF, g, 298.15 K) value adopted is -69.42 kcal·mol^{-1} (-290.453 ± 2.1 kJ·mol^{-1}).

Gaydon[11] and Herzberg[12] reported $D_0° = 114.2 \pm 6.9$ (4.95±0.3 eV) and < 122.2 kcal·mol^{-1} (5.3 eV), respectivley. Using JANAF $\Delta_f H°(298.15\ K)$ values for Na(g) and F(g), we obtain $\Delta_f H°$(NaF, g, 298.15 K) = -70.5 ± 5.8 and >-78.5 kcal·mol.$^{-1}$ Employing flame–photometric method, Bulewicz *et al.*[13] and Page and Sugden[14] derived $D_0° = 121 \pm 7$ and 119–120 kcal·mol^{-1} for NaF(g), which lead to $\Delta_f H°$(NaF, g, 298.15 K) = -77.3 ± 7 and -75 to -76 kcal·mol.$^{-1}$

Heat Capacity and Entropy

Veazey and Gordy[15] have measured the rotational transitions of NaF in the millimeter– and sub–millimeter–wave region with a high resolution molecular–beam absorption spectrometer. The derived values of ω_e, $\omega_e x_e$, B_e, α_e and r_e are adopted here.

Using the molecular beam electric resonance method, Bauer and Lew[16] measured the transition between the J = 0 and J = 1 rotational levels of $Na^{23}F^{19}$ in the three lowest vibrational states. Radio–frequency transitions for $Na^{23}F^{19}$ have been observed by Hollowell *et al.*[19] Infrared spectra of NaF have been analyzed by Snelson and Pitzer,[17] Ritchie and Lew,[18] and Baikov and Vasilevskii.[20] The molecular constants derived by the above authors are similar to the values adopted, except the value ω_e= 550 cm^{-1} [17] which is different from the value 536.1 cm^{-1} reported by Veazey and Gordy.[15]

Enthalpy of Formation

The dissociation energy has been calculated by many different techniques. The derived values range from 106.3 to 403.7 kJ·mol^{-1}. The values may be grouped into two types: (1) derived from a molecular orbital calculation and (2) extracted from reaction studies involving F_2O. We adopt D_0°(OF) = 18030 ± 850 cm^{-1} (215.687 ± 10 kJ·mol^{-1}) based on the experimental studies of Clyne and Watson,[1] Czarnowski and Schumacher,[2] Berkowitz *et al.*,[3] and Zhang *et al.*[4] These four studies are all dependent on the enthalpy of formation of OF_2(g) and are mass spectrometric studies except for the thermal decomposition of OF_2 by Czarnowski and Schumacher.[2] From the adopted value, we calculate $\Delta_f H°$(OF,g, 298K) = 109 ± 10 kJ·mol^{-1}. Additional data needed for the calculations presented here, e.g. thermal functions for the F(g) and F_2(ref), O(g) and O_2(ref), are taken from the JANAF Thermochemical Tables.[5]

Heat Capacity and Entropy

The spectroscopic results tabulated above are for the $^{16}O^{19}F$ isotopomer. Isotopic relationships[6] are used to convert the above constants to those for the normally occurring, i.e. natural abundance, species. The latter values are then used in the calculation of the thermal functions. Only the X state is included in the calculation of the thermal functions; a sum–over–states technique is used.

The ground state, $X^2\Pi_{3/2}$, has been characterized by Burkholder *et al.*[7] The observations were made using a high resolution Fourier transform spectrometer and a multiple reflection absorption cell equipped to study short–lived molecules under fast flow conditions. Hammer *et al.*[8] used a high resolution Fourier transform spectrometer to study the OF infrared chemiluminescence. This latter study, the results of which we have adopted, provided values which were slightly different from the Burkholder *et al.*[7] work.

The value of A, the splitting of the ground state, has been determined experimentally by five authors: McKellar[9] (177.3 ± 5.6 cm^{-1}), Dyke *et al.*[10] (160 ± 30 cm^{-1}), McKellar *et al.*[11] (177.3 cm^{-1}), Burkholder *et al.*[7] (198.3 ± 6.7 cm^{-1}), and Hammer *et al.*[8] (193.80 ± 0.97 cm^{-1}). We adopt the value of Hammer *et al.* as determined by high resolution Fourier transform spectroscopy.

An $A^2\Pi$ state is assumed to exist at approximately 35,000 cm^{-1} but has not been observed. This state would not contribute significantly to the thermal functions below 6000 K.

Titanium Fluoride Oxide (OTiF) IDEAL GAS M_r = 82.877803

$S°(298.15\ K)$ = [250.667] $J·K^{-1}·mol^{-1}$

$\Delta_f H°(0\ K)$ = [−430.918] $kJ·mol^{-1}$

$\Delta_f H°(298.15\ K)$ = [−433.211] $kJ·mol^{-1}$

Vibrational Frequencies and Degeneracies ν, cm^{-1}
[880](1)
[300](1)
[740](1)

Ground State Quantum Weight: [2] σ = 1
Point Group: [$C_{\infty v}$]
Bond Distances: Ti–O = [1.62] Å; Ti–F = [1.74] Å
Bond Angle: O–Ti–F = [180°]
Rotational Constant: B_0 = [0.170462] cm^{-1}

Enthalpy of Formation

$\Delta_f H°(0\ K)$ was estimated as −103 $kcal·mol^{-1}$ by Gordon.[1] $\Delta_f H°(298.15\ K)$ was then calculated.

Heat Capacity and Entropy

Molecular constants were estimated by Gordon.[1] Principal moment was 16.419 × 10^{-39} $g·cm^2$.

Reference

Enthalpy of Formation

The enthalpy of formation was calculated based on the molecular geometry optimization of Gosavi *et al.*[1] This calculation yielded the result Δ_fH(OFO) – Δ_fH(FOO) = 356 kJ·mol^{-1}. It is assumed that this calculated difference referred to 0 K. In contrast, Gole and Hayes[2] earlier calculated difference of >418 kJ·mol^{-1}.

Heat Capacity and Entropy

The molecular geometry adopted here is that used by Gosavi *et al.*[1] in their quantum mechanical calculations (6–31G basis sets). The structure was calculated to be bent with a O–F–O angle of [76.75°]. The bond length was calculated to be [1.5591]Å. The principle moments of inertia (in g·cm^2) are: I_A = 2.9573×10^{-39}, I_B = 4.9779×10^{-39}, and I_C = 7.9351×10^{-39}.

Gosavi *et al.*[1] examined the molecular geometry optimization of four electronic states of OFO at the RHF–SCF level with 6–31G and 6–31G* basis sets. In contrast, earlier calculations by Gole and Hayes[2] were based on a double–zeta sp basis set SCF total energy calculations as a function of the OFO bond angle. This latter study suggested a $^2B_1$ ground state with a bond angle of 128.22° (assuming a O–F bond distance of 1.19 Å).

The vibrational frequencies are estimated from the corresponding vibrational frequencies which describe the other OXO(g) molecules, where X = Cl and Br.

Enthalpy of Formation

The enthalpy of formation of O_2F(g) at 298.15 K, 25.4 ± 2 kJ·mol^{-1}, is based on six experimental results.[1-6] Two earlier studies[7,8] are not included in this analysis. The review by Lyman[4] recommended an enthalpy of formation value based on three experimental studies.[1,7,8] These six experimental studies and their recommended values are:

Author	$\Delta_f H°$(298 K), kJ·mol^{-1}	T/K of study	Technique
Lyman and Holland[1]	23.0 ± 1.7	298 K	Kinetic study of reaction F+O_2
Holland *et al.*[2]	24.1		Unpublished; kinetic study of reaction F+O_2
Shamonima and Kotov[3]	21.6	223–293 K	EPR measurement of rate constants
Lyman[4]	22.9		Review
Pagsberg *et al.*[5]	26.1 ± 2.1	295–359 K	Spectrokinetic study
Campuzano–Jost *et al.*[6]	24.7 ± 4	100–420 K	Spectrokinetic study

Heat Capacity and Entropy

The structure of this molecule is bent with a F–O–O angle of 111.2° based on the diode–laser spectrum as obtained by Yamada and Hirota.[9] The bond length is F–O = 1.649Å and O–O = 1.200 Å. Supporting structural information is available from the infrared study of McKellar *et al.*,[10] a microwave study by Bogey *et al.*,[11] and a laser magnetic resonance study by Bley *et al.*[12] The principle moments of inertia (in g·cm^2) are: $I_A = 1.0714 \times 10^{-39}$, $I_B = 8.3532 \times 10^{-39}$, and $I_C = 9.4246 \times 10^{-39}$.

There are numerous studies from which vibrational frequencies are derived: Yamada and Hirota,[9] Mckellar *et al.*,[10] Arkell,[13] Noble and Pimentel,[14] Spratley *et al.*,[15] Jacox,[16] and Kim and Campbell.[17] We adopt the recommendations of Jacox,[18] using gas phase values for ν_1 and ν_3 and the nitrogen matrix X value for ν_2.[15] Similar vibrational frequencies were recommended by Lyman[4] in an earlier review.

Lyman stated that the published absorption spectra of O_2F Glissman and Schumacher[19] and Matchuk *et al.*[20] indicated no electronic states at energies below the dissociation energy of the molecule. Jacox[18] in her review, discussed four absorption studies in which a maximum has been observed at 205nm by Chegodaev and Tupikov,[21] 420nm by Fessenden and Schuler,[22] and 445nm Matchuk *et al.*[20] Jacox[16] observed the onset of dissociation near 490nm. Only the X and A states are used in the calculation.

Enthalpy of Formation

There has been no report of a direct experimental determination of $\Delta_f H°$. Sufficient information is available, however, to allow a reasonable estimate of the P–F bond energy (D_0°) to be made.

linear Birge–Sponer extrapolation of the ground state vibrational constants leads to D''(LBX) = 4.90 eV. This value can be refined by taking into account the ionic character of the P–F bond. Using relationships developed by Hildenbrand,[1] we adjust the value of D''(LBX) to obtain D'' = 4.25 eV. A similar treatment of spectroscopic data[5] for related molecules (AlF, SiF, and ClF) which have well established bond energies indicates that the true D_0° value could be higher than D'' by roughly 0.3 eV. Additional support for this is provided by the results of two molecular orbital studies[2,3] which have led to estimates of D_0° of 4.5 eV and 4.65 ± 0.2 eV. The latter value, obtained from Hartree–Fock energies and estimated corrections for correlation effects, is believed to be reliable within the quoted uncertainty. A CNDO/2 MO study,[4] employing energy partitioning concepts, has led to a much higher estimate of D_0° equal to 5.17 eV.

We adopt D_0°(PF) = 4.60 ± 0.2 eV (106.08 kcal·mol^{-1}) which gives $\Delta_f H°$(PF) = −8.546 ± 5.0 kcal·mol^{-1} when combined with JANAF auxiliary data[5] for P and F. The adopted D_0° value lies midway between the well established bond energies[5] for SiF (130.3 kcal·mol^{-1}) and SF (81.2 kcal·mol^{-1}) and is near the mean bond energy (D = 109.1 kcal·mol^{-1}) in PF_5.[5] $\Delta_f H°$ at 298.15 K is −8.345 kcal·mol^{-1}.

Heat Capacity and Entropy

The thermal functions are calculated from the partition function $Q = Q_t \Sigma g_i Q_r^i Q_v^i \exp(-c_2\epsilon_i/T)$ in which Q_r^i and Q_v^i contain first order corrections for anharmonicity. The electronic and molecular constants are taken from the compilation of Suchard.[6] Values of $\omega_e x_e$ placed in brackets are estimates obtained from data on isoconfigurational states of SO ($A^3\Pi$[6]) and PF($B^3\Pi$). Our entropies may contain significant errors, amounting to several tenths of a cal K^{-1}·mol^{-1}, above 3500 K due to the omission of many unobserved electronic levels which have been predicted[7] to lie above the $b^1\Sigma$ state at 13353.91 cm^{-1}. In addition, Skolnik and Goodfriend[8] recently observed in emission a triple headed band system near 5600Å which was tentatively assigned to a $^3\Delta_{inv} - {}^3\Pi_{inv}$ transition of PF. These inverted triplet levels are also omitted since we are unable to estimate their term values with respect to the $X^3\Sigma^-$ ground state.

Our calculations essentially update and extend those previously made on PF by O'Hare.[9] The most significant difference is that our calculations are based on solid phosphorus (Red, V) as the reference state below 704 K rather than the ideal diatomic gas selected by O'Hare.[9]

Enthalpy of Formation

Harland *et al.*[1] and Torgerson and Westmore[2] reported the appearance potential of PF^+ from PF_3 as 21.0 ± 0.3 eV and 20.5 ± 0.2 eV, respectively. We use the mean value of $AP(PF^+/PF_3) = 20.75 \pm 0.3$ eV (478.50 kcal·mol^{-1}) in the expression $\Delta_r H°(0\ K) = AP\text{-}E^*$ for the process $PF_3(g) + e^- = PF^+(g) + 2\ F(g) + 2e^-$. With the assumption $E^* = 0$, the value of $\Delta_r H°(0\ K)$ gives $\Delta_f H°(PF^+, g, 0\ K) = 217.823 \pm 9.0$ kcal·mol^{-1} with $\Delta_f H°(PF_3, g, 0\ K) = -223.97 \pm 0.9$ kcal·mol^{-1} and $\Delta_f H°(F, g, 0\ K) = 18.36 \pm 0.4$ kcal·mol^{-1}.[3] We adopted this value. In the same paper, Harland *et al.*[1] also reported $AP(PF^+/PF_2CN) = 19.1 \pm 0.2$ eV which leads to $\Delta_f H°(PF^+, g, 0\ K) = 233.56 \pm 21.3$ kcal·mol^{-1}, in reasonable accord with the adopted result.

$\Delta_f H°$ at 298.15 K is 219.641 ± 9.0 kcal·mol^{-1}, and the adopted ionization potential (IP) is 9.82 ± 0.61 eV. This IP compares favorably with values predicted from quantum mechanical calculations. These have included (all in eV) 9.5 ± 0.2,[4] 9.6,[5] and 10.35.[6] The latter value is based on IP(P) = 10.98 eV which is 0.5 eV higher than the current best value of 10.486 eV.[7] Recalculation of the results of Companion and Hsia[6] gives IP(PF) = 9.85 eV.

The primary bond dissociation energy $D_0^\circ(PF^+)$ is calculated to be 121.5 kcal·mol^{-1} which can be compared with 106.1 kcal·mol^{-1},[3] in the neutral molecule. The stronger P–F bond in the ion is consistent with theoretical predictions[4–6] that the electron lost from PF occupies an antibonding orbital.

Heat Capacity and Entropy

The thermal functions are calculated from the partition function $Q = Q_t \Sigma g_i Q_r^i Q_v^i \exp(-c_2\epsilon_i/T)$ in which Q_r^i and Q_v^i contain first order corrections for anharmonicity. The electronic and molecular constants are taken from Douglas and Frackowiak[8] who observed one band system in the emission spectrum of PF^+ formed by passing a discharge through a mixture of PF_3 and He. We treat the ground state as two distinct electronic levels with a splitting of 323.95 cm^{-1}. This procedure gives functions which are slightly biased below 400 K. The uncertainty in the value of $S°(298.15\ K)$ includes this error. By analogy with the isoelectronic molecules SiF and PO,[3] other excited states are predicted to lie in the range 20000–30000 cm^{-1}. We prefer to omit these levels, but if they do exist our entropies could be slightly low above 4500 K.

Enthalpy of Formation

We calculate the enthalpy of formation at 0 K as the difference between $\Delta_f H°(PF, g, 0 K) = -8.55 \pm 5.0$ kcal·mol^{-1},[1] and the selected value of 1.1±0.5 eV (25.366 kcal·mol^{-1}) for the electron affinity (EA) of PF. The value of EA refers to the vertical electron detachment process $PF^-(g) = PF(g) + e^-$ and is taken from the molecular orbital study of O'Hare.[2] This value was obtained from Hartree Fock energies and estimated corrections for correlation effects. The estimated uncertainty in EA is 0.5 eV which should be adequate to cover the possibility that the adiabatic value is lower than the vertical EA. Other theoretical predictions of EA include 2.55 eV[3] and 1.4 eV.[4]

$\Delta_f H°$ at 298.15 K is −35.035 kcal·mol^{-1}, and the primary bond dissociation energy (Products P(g) + F^- (g)) is 53.1 kcal·mol^{-1}. The latter value can be compared with $D_0^\circ(PF)$ = 106.1 kcal·mol^{-1},[1] indicating that the P–F bond is much weaker in the anion relative to the neutral molecule. This is consistent with MO predictions[24] which indicate that the electron captured by PF occupies an antibonding orbital located primarily on the phosphorus atom.

Our thermal functions indicate that PF^- is thermodynamically stable with respect to dissociation (P + F^-) below 2500 K. These predictions agree qualitatively with the results of MacNeil and Thynne[5] who observed PF^- in the negative ion mass spectrum of PF_3. Their reported appearance potential, $AP(PF^-/PF_3)$ = 11.4 ± 0.1 eV, gives EA(PF) = −0.47 eV assuming that the dissociative electron capture process is $PF_3(g) + e^- = PF^-(g) + 2F(g)$. We believe this value is too low probably because of excess kinetic and/or excitation energies amounting to roughly 1.5 eV.

Heat Capacity and Entropy

The bond length and vibrational constants are assumed to lie between those for PF and SF.[1] The value of B_e is obtained from r_e. We calculate α_e from the other constants assuming a Morse potential function.

The ground state electronic configuration ($^2\Pi_{3/2}$), ground state splitting (A = 350 cm^{-1}), and excited state ($^2\Pi$) at 25000 cm^{-1} are estimated by analogy with those for the isoelectronic molecule SF.[1] The major source of error in our calculations below 500 K arises from the uncertainty in the ground state splitting. With A = 0 cm^{-1}, the value of $S°$(298.15 K) increases by 0.5 cal K^{-1}·mol^{-1}. At higher temperatures the differences in S become smaller, indicating that the uncertainty in the adopted entropies above 1000 K is less than 0.2 cal K^{-1}·mol^{-1}.

Thiophosphoryl Fluoride (PSF) IDEAL GAS M_r = 82.032163

$S°(298.15\ K) = [277.717 \pm 12.6]\ J \cdot K^{-1} \cdot mol^{-1}$

$\Delta_f H°(0\ K) = [-169.189 \pm 62.8]\ kJ \cdot mol^{-1}$

$\Delta_f H°(298.15\ K) = [-172.268 \pm 62.8]\ kJ \cdot mol^{-1}$

Vibrational Frequencies and Degeneracies ν, cm^{-1}
[940](1)
[740](1)
[400](1)

Ground State Quantum Weight: 1 $\sigma = 1$

Point Group: C_s

Product of the Moments of Inertia: $I_A I_B I_C = [7.999 \times 10^{-114}]\ g^3 \cdot cm^6$

Enthalpy of Formation

The $\Delta_f H°(298.15\ K)$ was estimated by Henderson and Scheffee.[1]

Heat Capacity and Entropy

The vibrational frequencies were estimated by comparison with the corresponding frequencies of PF(g), PS(g), and PF_2(g). The vibrational levels of PF_2(g) in turn were estimated by Gordon.[2] The entropy was estimated by Henderson and Scheffee.[1] The product of the moment of inertia was derived from the estimated entropy.

Enthalpy of Formation

Rosen[1] lists $D° = 84.0 \pm 2$ kcal·mol^{-1} derived from the mass spectrometric work of Zmbov *et al.*[2] The partial pressures and log K for the $PbF_2(g) + Pb(g) = 2PbF(g)$ reaction in the latter reference are inconsistent. 3rd law calculations show that the log K value corresponds to the heat of reaction given. The dissociation energy calculated by the linear Birge–Sponer extrapolation of the adopted ground state vibrational constants, as derived from emission and absorption spectra (ν, 0–13),[3, 4] is 3.44 eV. Correcting this value for the ionic character of PbF as suggested by Hildenbrand[5] gives $D_0° = 3.64$ eV (83.9 kcal·mol^{-1}). The upper limit of the value recommended by Gaydon[6] (3 ± 0.5 eV) falls at 80.7 kcal·mol^{-1}. An intercomparison of the dissociation energies of the lead,[7] mercury,[1] and potassium[7] monohalides indicates that $D_0° = 84.0 \pm 2$ kcal·mol^{-1} is reasonable. Combining this with $\Delta_f H°$(Pb, g, 0 K) = 46.91 ± 0.13 kcal·mol^{-1},[7] and $\Delta_f H°$(F, g, 0 K) = 18.36 ± 0.40 kcal·mol^{-1},[7] gives $\Delta_f H°$(PbF, g, 0 K) = −18.73 ± 2.5 kcal·mol^{-1}. We adopt $\Delta_f H°$(PbF, g, 0 K) = −18.70 ± 2.5 kcal·mol^{-1} which is consistent with the above. $\Delta_f H°$(PbF, g, 298.15 K) = −19.18 ± 2.5 kcal·mol^{-1} is calculated from $\Delta_f H°$(0 K).

Heat Capacity and Entropy

The vibrational constants, the electronic states and levels, and the rotational constant are those recommended in Rosen[1] with the following modifications. The first excited state, unassigned in Rosen,[1] is tentatively classed as a $^2\Sigma$ state in accordance with the preference for $^2\Sigma$ over $^2\Delta$ expressed by Barrow *et al.*[8] If the state is $^2\Delta$ rather than $^2\Sigma$, the entropy is increased by 0.005 cal K^{-1}·mol^{-1} at 4000 K and 0.05 cal K^{-1}·mol^{-1} at 6000 K. The *C* and higher electronic states[1] have been omitted; inclusion increases the entropy only by approximately 0.005 cal K^{-1}·mol^{-1} at 6000 K. The adopted $B_e = 0.2288\ cm^{-1}$ is obtained by an approximate correction to $B_0 = 0.2281\ cm^{-1}$ given in Rosen,[1] and $r_e = 2.058$ Å calculated from B_e compares with $r_0 = 2.061$ Å given in Rosen.[1] The value for α_e is calculated assuming a Morse potential function.

Enthalpy of Formation

Hildenbrand[1] has investigated the isomolecular reaction $CS_2(g) + 2SF(g) = CF_2(g) + 2S_2(g)$ by mass spectrometry. The various molecular species were found to be formed as products of the reaction of gaseous SF_6 with graphite at temperatures in the range 1436–1611 K. This study employed three different effusion cell configurations which were used to optimize the reaction conditions, and ion abundances for each species were measured at 2 eV above their appearance potentials in order to eliminate fragmentation effects. We analyze the reported equilibrium data by the 2nd and 3rd law methods with the results being presented below.

Series	Cell Configuration	Data Points	T/K	$\Delta_f H°$(298.15 K), kcal·mol^{-1} 2nd law	3rd law	Drift cal K^{-1}·mol^{-1}	$\Delta_f H°$(298.15 K) kcal·mol^{-1}
1	Mo cell/C liner/packed	2	1529–1611	−11.6	−16.2	2.9	3.2
	with C cloth				±0.3		±1.2
3	C cell/wound Pt wire	4	1436–1564	6.8	−16.0	−15.1	3.1
					±1.8	±5.0	±2.0
3	C cell/Pt partition/packed	7	1478 1588	−37.2	−15.8	13.9	3.0
	with C cloth and Pt wire				±1.4	±5.0	±1.8

The three cell configurations used by Hildenbrand[1] yield almost identical 3rd law $\Delta_f H°$ values. We adopt the mean value of 3.1±1.5 kcal·mol^{-1}. This value corresponds to a $D_0°$ of 81.2±2.0 kcal·mol^{-1} which is close to the average bond energies (80.0 kcal·mol^{-1}) for SF_4 and SF_3[2]. Other reported $D_0°$ values include 96.9 kcal·mol^{-1} [3] and <76.1 kcal·mol^{-1}.[4] The former value is based on Hartree Foch binding energies[3] which were combined with an estimate of the extra molecular correlation energy. This estimate now appears to be about 20% too high. The upper limit value for $D_0°$ was obtained from predissociation observed in the $A^2\Pi$ state by Di Lonardo and Trombetti.[4]

Heat Capacity and Entropy

The electronic states and levels (T_e) are taken from the recent compilation of Barrow.[5] His results were derived from the spectral measurements of Di Lonardo and Trombetti.[4] Further confirmation that the ground state is inverted $^2\Pi$ is provided by the results of an analysis of the gas phase electron resonance spectra by Carrington *et al*.[6] The rotational constant (B_e) is calculated from the microwave data (B_{eff}) of Amano and Hirota.[7] Other values for B_e determined from EPR[6] measurements and from a rotational analysis[4] of the $A^2\Pi$ $X^2\Pi$ band system agree with the microwave results but are less precise. The value of r_e is calculated from B_e.

The ground state vibrational constants have not been determined experimentally. O'Hare[8] computed Hartree Fock total energies for the ground states of NF, SiF, PF, and SF and derived spectroscopic constants for each monofluoride by a Dunham analysis. He adjusted the computed values for SF for differences found between calculated and experimental data for the other three monofluorides. We adopt his predicted vibrational constants along with his computed value for α_e. We do not include the rotational and vibrational constants[4, 5] for the $A^2\Pi$ state since they have a negligible effect.

Thermal functions have been previously reported for SF by Wilkins[9] and O'Hare.[10] These two sets of functions agree reasonably well, and presumably they are both based on a ground state quantum weight of 2. Our entropies are consistently higher than the literature data[9, 10] at all temperatures by roughly 1.0 1.5 cal K^{-1}·mol^{-1}. This increase can be attributed primarily to the entropy contribution from the $X\ ^2\Pi_{1/2}$ state which lies at 398 cm^{-1}.

Enthalpy of Formation

The electron impact appearance potential of SF^+ from SF has been measured by Hildenbrand[1] as 10.09 ± 0.1 eV. Normally, this measured AP would be identical to the vertical ionization potential of SF; however, formation of SF^+ involves the loss of an antibonding electron which appears to be situated primarily on the sulfur atom (IP(S) = 10.36 eV,)[2]. Thus, the geometrical changes produced upon ionization should be minimal, and therefore, the measured AP is probably very close to the true (adiabatic) ionization potential, as suggested by Hildenbrand.[1] We employ the experimental IP value as the heat of reaction, $\Delta_r H°$ = 232.68 ± 2.3 $kcal·mol^{-1}$, for the process $SF(g) + e = SF^+(g) + 2e^-$ at 0 K, and we calculate $\Delta_f H°(SF^+, g, 0\ K)$ = 235.6 ± 4.0 $kcal·mol^{-1}$ by combining the value of $\Delta_r H°(0\ K)$ with $\Delta_f H°(SF, g, 0\ K)$ = 2.9 ± 1.5 $kcal·mol^{-1}$.[1,3] Independent values of IP include 10.0 eV[4] and 9.9 eV.[5] Both of these values were obtained from semiempirical molecular orbital calculations and are in excellent agreement with the results adopted here.

Earlier electron impact studies which can also be used to derive $\Delta_f H°$ of SF^+ have been previously analyzed by O'Hare and Wahl.[6] We do not reanalyze these results since their analysis[6] has shown that the data are seriously in error.

Heat Capacity and Entropy

As discussed in the enthalpy of formation section, one would expect that the bonding in SF^+ is probably not very different from that in SF, since the ionizing orbital is antibonding. Additional support for this is provided by the fact that the bond dissociation energies for SF^+ (87.4 $kcal·mol^{-1}$) and SF (81.2 $kcal·mol^{-1}$) are very similar. In addition, SF^+ is isoelectronic with PF, and one might therefore expect that the molecular characteristics of these two isoelectronic molecules would be quite similar. We estimate the vibrational and rotational constants to be intermediate between those for SF^3 and PF.[7] By analogy with other twelve valence electron molecules,[7] we predict that the ground state is $^3\Sigma$ and expect several excited states to exist below 35000 cm^{-1}. The two singlet levels are estimated from those observed for NF and O_2.[7] We also include a triplet level at 30000 cm^{-1} based on that observed for PF.[7] We assume that the vibrational and rotational constants for the excited states are identical with those for the ground state since a comparison of the constants[7] that are available for the various states of NF and PF shows that they are not significantly different. The uncertainty in our value of $S°(298.15\ K)$ is estimated as ±2.2 cal $K^{-1}·mol^{-1}$ and arises primarily from the effect of the ground state quantum weight. If the SF^+ ground state is singlet, then our entropy value at 298.15 K should be decreased by 2.18 cal $K^{-1}·mol^{-1}$. The electronic contribution to the entropy from the estimated excited states is negligible below 2000 K but increases to 0.4 cal $K^{-1}·mol^{-1}$ at 4500 K.

$B_e = [0.45620]\ cm^{-1}$ $\quad \alpha = [0.0046]\ cm^{-1}$ $\quad r_e = [1.76]$ Å

Enthalpy of Formation

The adopted value of $\Delta_f H°(0\ K) = 43.2 \pm 13.0\ kcal·mol^{-1}$ is calculated as the difference between the $\Delta_f H°(SF, g, 0\ K) = 2.94 \pm 1.5\ kcal·mol^{-1}$ [1] and an estimated EA (SF) = 2.0 ± 0.5 eV (46.121 $kcal·mol^{-1}$). We estimate EA based on a consideration of trends in the electron affinities for other S–F Species.[1] These data follow a regular pattern among the even– and odd– electron molecules, with the odd electron molecules having, as expected, the higher EA's. Within each even– and odd–electron series, the EA values become progressively larger as the number of fluorine atoms in the ion is increased. Our $\Delta_f H°(0\ K)$ value corresponds to a fluoride ion affinity IA (S) and bond dissociation energy ($SF^- = S + F^-$) of 48.9 ± 13.5 $kcal·mol^{-1}$. Correcting $\Delta_f H°(0\ K)$ to a temperature of 298.15 K, we obtain the value of −44.6 $kcal·mol^{-1}$.

Several pieces of information are available which tend to provide support for our estimated EA value. Formation of SF^- involves the addition of an electron to an antibonding orbital of SF^2 which is located primarily on the sulfur atom. It is reasonable, therefore, to assume that EA(SF)≃EA(S) = 2.0772 ± 0.005 eV.[3] O'Hare[2] has pointed out that Koopmans' theorem[4] gives reliable estimates of electron affinities and ionization potentials provided that the parent molecule or ion have a closed shell electronic configuration. Application of this theorem to SF^- which has the required closed–shell structure leads to EA = 1.7 eV.[2] Other estimates of EA based on MO calculations have included (all in eV) 2.8,[5] 2.5 ± 0.5,[6] and <3.2.[2]

JANAF data[1] suggest that SF^- should be reasonably stable at moderate temperatures, with dissociative ionization becoming thermodynamically favorable above 2000 K. These predictions are supported qualitatively by the observations of Harland and Thynne[7, 8] who have identified SF^- in the negative ion mass spectra of SF_4, SF_6, and SF_5Cl. The temperature of the ion source was reported as around 325 K.[8]

Heat Capacity and Entropy

The additional antibonding electron in SF^- should weaken the bonding in the ion relative to the parent molecule, as evidenced by a reduction (~32 $kcal·mol^{-1}$) in the S–F bond strength for SF when compared with that for SF.[1] In addition, MO calculations[9] on OF and OF^- show that the O–F bond length in OF increases by 0.159 Å upon forming the negative ion. We apply this difference to $r_e(SF)$ = 1.5967 Å,[1] and we obtain $r_e(SF^-)$ = 1.76 Å. The value of B_e is calculated from our estimate of r_e. We use Badger's rule[10] to estimate a value for ω_e. We write the equation in the form $\omega_e^2 = 3.159 \times 10^6/\mu(r_e\ d_{ij})$,[3] and we set d_{ij} equal to 0.8833 based on molecular data for ClF.[11] Barrow and Caunt[12] have shown that the product $x_e\mu^{1/2}$ is reasonably constant for a series of similar molecules. Using $x_e\mu^{1/2} = 0.0279$ from ClF,[11] we calculate x_e= 0.008068 and $\omega_e x_e = 5.06\ cm^{-1}$ for SF^-. The value of α_e is obtained from the other constants, assuming a Morse potential function.[13]

The electronic states and levels are estimated by analogy with those for ClF.[11] The effect of the triplet level at 20000 cm^{-1} on our entropies is insignificant below 3000 K, but this level does contribute 0.15 cal $K^{-1}·mol^{-1}$ to S at 4500 K. We assign an uncertainty of ±0.2 cal $K^{-1}·mol^{-1}$ to the value of $S°(298.15\ K)$ based on conservative estimates of the uncertainties in the vibrational and rotational data.

Enthalpy of Formation

Ehlert and Margrave[1] have studied mass spectrometrically the reaction $Si(g) + SiF_2(g) \rightarrow 2\ SiF(g)$ by monitoring the intensities of the Si^+, SiF_2^+ and SiF^+ ions in an equilibrium system containing CaF_2 and Si. The ionization cross sections are assumed to cancel so that equilibrium constants can be obtained directly from the ion intensities. Eleven data points were reported in the 1395 to 1543 K range. We have analyzed their data using present JANAF functions[2] and obtain $\Delta_r H°(298.15\ K) = 23.5 \pm 3$ kcal·mol^{-1} by the 3rd law technique with a drift of -0.8 ± 11 cal $K^{-1} \cdot mol^{-1}$; the 2nd law value is 23.9 ± 7 kcal·mol^{-1}. Farber[6] also has determined equilibrium constants mass-spectrometrically for the $Si(g) + SiF_2(g) = 2\ SiF(g)$ reaction; ten data points over a 1590 to 1782 K range were obtained. Our analysis yields a 3rd law $\Delta_r H°(298.15\ K) = 21.08 \pm 0.59$ kcal·mol^{-1} with a drift of -1.9 ± 1.5 cal $K^{-1} \cdot mol^{-1}$; the 2nd law value is 24.18 ± 2.5 kcal·mol^{-1}. The two groups of data are in good agreement. We adopt an average value and calculate $\Delta_f H°(SiF, g, 298.15\ K) = -4.8 \pm 3$ kcal·mol^{-1}.

$D_0° = 130 \pm 4$ kcal·mol^{-1} is calculated from the resulting $\Delta_f H°(0\ K)$ and auxiliary data.[2] Johns and Barrow[3] recommended 125 ± 10 kcal·mol^{-1} from Birge–Sponer extrapolations of several states. Gaydon[4] preferred 115 ± 12 kcal·mol^{-1} from a Birge–Sponer extrapolation of the ground state.

Heat Capacity and Entropy

The molecular constants and electronic levels are those given by Suchard.[5] Five higher levels are given but are not used since they do not significantly affect the calculations. The ground state is treated as two distinct levels due to the splitting of this state as expressed by the spin coupling constant (A=161.93 cm^{-1}). This approximation gives slightly biased results at lower temperatures. An error of ± 0.04 cal $K^{-1} \cdot mol^{-1}$ has been assigned to $S°(298.15\ K)$ to allow for this.

Enthalpy of Formation

Equilibrium constants for four dissociation equilibria have been determined from observations made on the condensed phase systems SrF_2–B,[1] SrF_2–Al,[2] and SrF_2–BaF_2–Al[2] by the mass spectrometric Knudsen effusion method. Enthalpies of reaction have been calculated from these Kp data by both the 2nd and 3rd law methods. Results of our analysis are given below, using JANAF auxiliary data.[4] Also included below is a value for the enthalpy of dissociation of SrF which was determined from spectrophotometric studies[3] of reaction equilibria in H_2–O_2–N_2 flames.

Source	Reaction	T/K	Data Points	$\Delta_f H°$(298.15), kcal·mol^{-1} 2nd law	3rd law	Drift cal K^{-1}·mol^{-1}	$\Delta_f H°$(298.15 K) kcal·mol^{-1}
Hildenbrand[1]	A	1476–1585	10	23.4	25.1±0.9	1.2±4.7	−70.1±2.7
Hildenbrand[1]	B	1436–1525	9	4.3	2.0±0.7	−1.5±4.0	−71.0±1.0

Ehlert *et al.*[2]	D	1125–1292	10	127.6	−116.5±1.5	9.1±2.7	−67.6±1.3
Ryabova and Gurvich[3]	E			132 ± 7			−73.9±8.0

Reactions: (A) $2Sr(g) + BF_3(g) = 2SrF(g) + BF(g)$ (D) $2SrF(g) = Sr(g) + SrF_2(cr)$

(B) $Sr(g) + SrF_2(g) = 2SrF(g)$ (E) $SrF(g) = Sr(g) + F(g)$

(C) $Sr(g) + BaF(g) = Ba(g) + SrF(g)$

[a]One point rejected due to failure of a statistical test.

It is believed that the Kp data for the three homogeneous reactions (A, B, and C) are more reliable than those for the heterogeneous reaction (D) due to the need for a machine calibration constant which appears in the equilibrium expression for the latter. Ehlert *et al.*[2] determined this constant from vaporization experiments performed with silver contained in their Knudsen cell. This belief is further substantiated by the appearance of the rather large positive drift in the third law analysis of their Kp data for reaction (D). Also, it is felt that the $\Delta_f H°$ value obtained from the flame spectrophotometric studies[3] is perhaps somewhat less reliable than the three values derived from the Kp data for the homogeneous reactions. Thus, a median value $\Delta_f H°$(SrF, g, 298.15 K) = −70.4±2.0 kcal·mol^{-1} of the latter results is adopted. The adopted value corresponds to a dissociation energy of $D_0°$ (Sr–F) = 127.7 kcal·mol^{-1} (5.54 cal K^{-1}·mol^{-1}).

Spectroscopic values for $D_0°$ based on a linear Birge–Sponer extrapolation of the ground state ($X^2\Sigma$) vibrational levels (v, 0–4) have been reported as 3.2[5] and 3.5 eV.[6] However, it is well established now that the linear extrapolation[5, 6] generally underestimates $D_0°$ if the binding of the molecule is partially ionic. Based on the ionic character correction suggested by Hildenbrand,[6] these values adjust to 4.9 and 5.4 eV. The latter value is now in reasonable agreement with the adopted thermochemical value. Other spectroscopic values[7] include 4.6 (from $X^2\Sigma$), 4.7 (from $A^2\Pi$), and 5.2 eV (from $C^2\Pi$). The products of dissociation from the two excited states of SrF were assumed to be $Sr(^3P) + F(^2P)$.

Heat Capacity and Entropy

The spectroscopic data with the exception of the value for α_e are those given by Rosen.[8] α_e is calculated from the other constants assuming a Morse potential function. The electronic states and levels are also taken from the compilation of Rosen.[8]

Enthalpy of Formation

The appearance potential of SrF^+ from SrF(g) has been measured mass spectrometrically by Hildenbrand,[1] Green *et al.*[2] and Ehlert *et al.*[3] as 5.0 ± 0.3 eV, 4.9 ± 0.3 eV, and 5.2 ± 0.3 eV, respectively. For the process $e^- + SrF(g) \rightarrow SrF^+(g) + 2e^-$, the corresponding $\Delta_f H°(SrF^+, g, 0\ K)$ are derived to be 45.3 ± 9.0, and 49.9± 9.0 $kcal·mol^{-1}$ with $\Delta_f H°(SrF, g, 0\ K) = -70.0 \pm 2.0\ kcal·mol^{-1}$.[4]

Hildenbrand[1] has also reported AP = 13.0 ± 1.0 eV for SrF^+ from $SrF_2(g)$. Green *et al.*[2] obtained an ionization efficiency curve for SrF^+ which extrapolates (high–energy portion) to 10.5 eV at zero ion current. Assuming the process to be $e^- + SrF_2(g) \rightarrow SrF^+(g) + F(g) + 2e^-$, we obtain $\Delta_f H°(SrF^+, g, 0\ K)$ equal to 98.7 ± 25.0 and 41.1 $kcal·mol^{-1}$ by combining the above results with $\Delta_f H°(SrF_2, g, 0\ K) = 182.7 \pm 1.0$ $kcal·mol^{-1}$ and $\Delta_f H°(F, g, 0\ K) = 18.36 \pm 0.4\ kcal·mol^{-1}$.[4]

The adopted $\Delta_f H°(0\ K)$ is based on the three mass spectral results[1, 2, 3] for the direct ionization process of SrF(g). The value of $\Delta_f H°$ at 298.15 K is 47.1 ± 10.0 $kcal·mol^{-1}$, and the corresponding ionization potential for SrF(g) is 5.03 eV.

Heat Capacity and Entropy

The internuclear distance (r_e) is the value estimated by Barrow and Beale[5] from spectroscopic work on SrF. The value of ω_e is calculated from Badger's rule[6] which can be written in the form $\omega_e^2 = 3.159 \times 10^6/\mu(r_e - d_{ij})$.[3] Molecular data for the ground states of SrF,[4] SrO,[7] and RbF[8] were used to determine the constant d_{ij}. The product $x_e\mu^{1/2}$ has been shown to be constant within a group of similar molecules by Barrow and Caunt.[9] Since $\mu^{1/2}(SrF^+) \cong \mu^{1/2}(SrF)$, we assume $x_e(SrF^+) = x_e(SrF)$ and obtain $\omega_e x_e$ equal to 2.42 cm^{-1} with our estimated value ω_e = 561 cm^{-1}. The value of α_e is obtained from the other constants assuming a Morse potential function.

SrF^+ has eight valence electrons; thus, the ground state configuration ($^1\Sigma^+$) and electronic level for the B state are estimated from those for the isoelectronic molecule SrS.[7] By analogy with the gaseous alkaline earth oxides,[10] C_2,[4] BeS,[11] and BaS,[12] low lying triplet states are to be expected. The two estimated triplet levels are based on those which have been observed directly in C_2,[4] BeS,[11] and indirectly (through perturbative effects) in BaS.[12] Also included are additional states at 12,000 cm^{-1} ($^1\Pi$), 15,000 cm^{-1} ($^1\Delta$), and 18,000 cm^{-1} ($^1\Sigma$). These three levels are also estimated from those for C_2,[4] Bes,[11] and BaS.[12] The adopted electronic entropies are believed to represent minimal values. Probable upper limits for the electronic contributions can be established by decreasing the two triplet levels to 1000 cm^{-1} ($^3\Pi$) and 5000 cm^{-1} ($^3\Sigma$) and neglecting the other excited states. This increases the entropy by 3.9 cal $K^{-1}·mol^{-1}$ and 2.6 cal $K^{-1}·mol^{-1}$ at 2000 K and 4000 K, respectively.

Enthalpy of Formation

The enthalpy of formation, $\Delta_f H°$(TiF, g, 298.15 K), is calculated from the dissociation energy. The dissociation energy is estimated as 148 ± 6 kcal·mol^{-1} using the corresponding quantity for TiF_2(g) and the relation $D_0°(MF)/\Delta_{at}H°(MF_2) = 0.46 \pm 0.02$ which Zmbov and Margrave[1] found held for other mono– and di–fluorides.

Heat Capacity and Entropy

The vibrational frequency, ω_e, and anharmonic vibrational term, $\omega_e x_e$, are estimated from those of the alkali and mercury monohalides. The interatomic distance, r_e, is estimated from those of TiCl(g), TiF_2(g) and TiF_3(g). B_e is calculated from r_e. The ground state term and electronic levels are estimated from the ground state multiplet of Ti^+.[2]

Enthalpy of Formation

The enthalpy of formation, $\Delta_f H°$(WF, g, 298.15 K) = 92.3 kcal·mol^{-1}, is calculated from the bond dissociation energy $\Delta_{at} H°$(WF, 298.15 K) = 130 ± 15 kcal·mol^{-1}. This value of $\Delta_{at} H°(298.15\ K)$ is estimated to be slightly higher than the average bond dissociation energy of WF_6(g) by analogy with the WCl_x system.

Heat Capacity and Entropy

The bond distance is estimated to be the same as that in WF_6(g). This distance is then used with Guggenheimer's[1] relation to calculate the fundamental vibrational frequency, ω_e.[1] The anharmonicity correction x_e is estimated roughly by assuming $x_e = \omega_e/4(D_0^o + 0.5\ \omega_e) = 0.0042$. The rotational constant, B_e, is calculated from the estimated bond distance. The value of α_e is calculated form the Morse potential function.

The ground state configuration, low lying electronic levels and their quantum weights are estimated based on the tentative molecular orbital diagram for TaO given by Weltner and McLeod.[2] Using this scheme, we obtain the ground state configuration as $\Pi^4\sigma\delta^4$ which yields a $^2\Sigma$ state. Higher levels are considered to be formed by transition to Π^* antibonding orbitals, and by analogy with TaO these are assumed to lie in the 15000 cm^{-1} region. The degeneracy of these levels is estimated roughly from the large number of possible configurations.

Enthalpy of Formation

Based on $[D_0°(ZrF)/\Delta_{at}H°(ZrF_2)] = 0.46$, as indicated by recent work on the fluorides of Groups II and IV elements,[1, 2, 3, 4, 5] and $\Delta_{at}H°(ZrF_2) = 318.1\ kcal·mol^{-1}$, the $D_0°(ZrF)$ is calculated as 146.3 $kcal·mol^{-1}$. Using $\Delta_f H°(ZrF, g, 0\ K) = 147.99$, $\Delta_f H°(F, g, 0\ K) = 18.36$, and $D_0°(ZrF, g) = 146.3\ kcal·mol^{-1}$, we derive $\Delta_f H°(ZrF, g, 0\ K) = 20.0$ or $\Delta_f H°(ZrF, g, 298.15\ K) = 19.8 \pm 5\ kcal·mol^{-1}$ (82.843 ± 20.9 $kJ·mol^{-1}$) which is adopted.

The $\Delta_f H°(ZrF, g, 298.15\ K)$ was evaluated as approximately 16 ± 5 $kcal·mol^{-1}$ by Murad and Hildenbrand,[8] employing a different $\Delta_{at}H°(ZrF_2)$ value. Their value is in agreement with the adopted one, within the assigned uncertainty.

Heat Capacity and Entropy

The ground state configuration is taken from the ground state multiplet of Zr^+.[6] The electronic levels are estimated as three times higher than those of TiF(g) and the quantum weights are assumed to be the same. ω_e is taken to be approximately the same as the ZrF_2 stretching frequency ν_1 for ZrF_4(g). B_e is calculated from the formula $B_e = 2.799076 \times 10^{-39}/I_e$ where $I_e = \mu r_e$, μ = reduced mass of ZrF(g), $r_e = 1.90$ Å which is estimated from those of ZrF_4, CF_4, CF and other related gaseous molecules, α_e is derived from B_e, ω_e and $\omega_e x_e$ (estimated), according to the method suggested by Herzberg.[7]

Heat of Formation

Zero by definition. Refer to monatomic fluorine gas table for a discussion of the discussion energy.

Heat Capacity and Entropy

The thermal functions are calculated using a direct summation technique. Due to the absence of known low lying bound excited states (i.e. <93000 cm^{-1}) only the ground state is included in the calculation.

The G(v), B_v and D_v spectroscopic constants for the ground state and the dissociation energy were determined by Colbourn *et al.*[1] These are used in the computation as given (and not as the usual fitting coefficients ω_e, $\omega_e x_e$, etc.). The rotational levels are weighted in accordance with the nuclear spin–rotation interaction[5] as follows: even J weight = 0.75, odd J weight = 0.25. Also, the rotational levels are extrapolated to high J values according to the method of Khachkuruzov[6] who proposed a simpler form of Wooley's method.[7] Note that there is only one stable isotope of fluorine, ^{19}F.

The so-called quasibound rotational levels above the dissociation limit[2,3] are also included. For a given vibrational quantum number, v, the summation over rotational states is carried out up to a rotational quantum number, J, given by $J = J_{lim}(1-v/v_{max})$ where J_{lim} amd v_{max} were determined by Gurvich *et al.*[4] to be 178 and 23, respectively. Our adopted value for S°(298.15 K) differs from values recommended by CODATA,[9] Gurvich *et al.*[3] and Wagman *et al.*[11] by less than 0.01 J K^{-1}·mol^{-1}. For this comparison, the entropy values reported by CODATA[9] and Gurvich *et al.*[3] are increased by 0.1094 J K^{-1}·mol^{-1}to account for a change in the standard–state pressure from 1 atm to 1 bar.

Phase Data

Hultgren *et al.*[8] had recommended the α→β transition temperature, 45.55 K, the triple point, 53.48 K (0.000249 atm) and the boiling point, 84.95 K (1 atm). These values should prove reasonably accurate, although they have not been evaluated by the present authors, and are furnished for the convenience of the reader. As a result of the low values, the reference state for fluorine is chosen to be the ideal diatomic gas at all temperatures. This may differ from the choice of other authors.

PREVIOUS: June 1977 (1 atm) CURRENT: June 1982 (1 bar)

$S°(298.15\ K) = 86.985 \pm 0.17\ J \cdot K^{-1} \cdot mol^{-1}$
$T_{fus} = [1373]\ K$

$\Delta_f H°(0\ K) = 705.266 \pm 41.8\ kJ \cdot mol^{-1}$
$\Delta_f H°(298.15\ K) = 705.841 \pm 41.8\ kJ \cdot mol^{-1}$
$\Delta_{fus} H° = [51.882]\ kJ \cdot mol^{-1}$

Enthalpy of Formation

The equilibrium pressures for the reaction $FeF_2(cr) + H_2(g) = Fe(cr) + 2HF(g)$ have been measured by Jellinek and Rudat[1] at 773, 873 and 973 K. The enthalpy change of the reaction, $\Delta_r H°(298.15\ K)$, was evaluated by the 2nd and 3rd law methods to be 27.19 and 39.08 $kcal \cdot mol^{-1}$, respectively. Based on the 3rd law value of $\Delta_r H°(298.15\ K)$, the $\Delta_f H°(FeF_2, cr, 298.15\ K)$ was calculated to be 168.7 ± 10 $kcal \cdot mol^{-1}$. The drift in the 3rd law values of $\Delta_r H°(298.15\ K)$ was evaluated to be 13.3 ± 1.8 cal $K^{-1} \cdot mol^{-1}$.

Heat Capacity and Entropy

The low temperature (11.33–307.30 K) heat capacities were determined by Catalano and Stout.[2] The heat capacities above 307 K were estimated by comparison with those of $FeCl_2(cr)$, $MgCl_2(cr)$ and $MgF_2(cr)$. The value of $S°(298.15\ K)$ was obtained from Catalano and Stout,[2] in which a sharp maximum $C_p°$ of 17.8 cal $K^{-1} \cdot mol^{-1}$ at 78.35 K was reported. The $S°(298.15\ K)$ value was based on $S°(15\ K) = 0.039$ cal $K^{-1} \cdot mol^{-1}$.

Fusion Data

T_{fus} was estimated as 1100°C based on the data reported by Biltz and Rahlfs.[3] The value of $\Delta_{fus} H°$ was calculated using $\Delta_m S° = 9$ cal $K^{-1} \cdot mol^{-1}$ which was assumed to be the same as the corresponding value for $MgF_2(cr)$.

Sublimation Data

The value of $\Delta_{sub} H°(298.15\ K) = 316.31 \pm 8.4\ kJ \cdot mol^{-1}$ was obtained from Margrave.[4] See $FeF_2(g)$ table for details.

PREVIOUS: CURRENT: September 1965

$S°(298.15\ K) = [92.537]\ J·K^{-1}·mol^{-1}$
$T_{fus} = [1373]\ K$

$\Delta_f H°(298.15\ K) = [-674.549]\ kJ·mol^{-1}$
$\Delta_{fus}H° = [51.882]\ kJ·mol^{-1}$

Enthalpy of Formation

$\Delta_f H°(FeF_2, l, 298.15\ K)$ is calculated from $\Delta_f H°(FeF_2, cr, 298.15\ K)$ by adding the enthalpy of fusion, $\Delta_{fus}H°$, and the difference in enthalpy, $H°(1373\ K)–H°(298.15\ K)$, between the crystal and liquid.

Heat Capacity and Entropy

The heat capacity for FeF_2(l) is estimated by comparison with those for $FeCl_2$(cr), $MgCl_2$(cr), MgF_2(cr), $CaCl_2$(cr) and CaF_2(cr). The $C_p°$ (FeF_2, l) value is assumed to be constant in the temperature range, 298.15–3000 K. $S°(298.15\ K)$ is calculated in a manner analogous to that used for the enthalpy of formation.

Fusion Data

Refer to the crystal table for details.

Vaporization Data

$T_{vap} = 2110$ K is calculated as the temperature at which the fugacity of the reaction $FeF_2(l) = FeF_2(g)$ is 1 atm. The difference between $\Delta_f H°$ for FeF_2 (l) and FeF_2(g) at T_{vap} is $\Delta_{vap}H° = 224.43\ kJ·mol^{-1}$.

Enthalpy of Formation

The rate of sublimation of FeF_2(cr) was measured between 965 and 1149 K by the Knudsen technique employing the high temperature magnetic mass spectrometer by Margrave.[1] The only vapor species of importance is FeF_2(g). From the vapor pressure data, the 3rd law enthalpy of sublimation, $\Delta_{sub}H°(298.15\ K)$, was reported as 75.6 ± 2.0 kcal·mol^{-1}. The sum of the values $\Delta_{sub}H°(298.15\ K)$ and $\Delta_f H°(298.15\ K)$ for FeF_2(cr) is $\Delta_f H°(FeF_2, g, 298.15\ K)$.

Heat Capacity and Entropy

The molecular structure was assumed to be linear. The Fe–F bond distance was estimated from that in FeF_2(cr) reported by Baur.[2] The vibrational frequencies, ν_1 and ν_3, were estimated by Brewer *et al.*[3] The values of ν_2, electronic levels and quantum weights were estimated by comparison with those for $FeCl_2$(g). See the ideal gas table for details.

PREVIOUS: September 1965 (1 atm) CURRENT: September 1965 (1 bar)

$S°(298.15\ K) = 104.264 \pm 0.4\ J \cdot K^{-1} \cdot mol^{-1}$
$T_{trs} = 469.85\ K$
$T_{fus} = 511.95\ K$

$\Delta_f H°(0\ K) = -926.386 \pm 1.26\ kJ \cdot mol^{-1}$
$\Delta_f H°(298.15\ K) = -931.233 \pm 1.26\ kJ \cdot mol^{-1}$
$\Delta_{trs} H° = 11.221 \pm 0.04\ kJ \cdot mol^{-1}$
$\Delta_{fus} H° = 6.619 \pm 0.013\ kJ \cdot mol^{-1}$

Enthalpy of Formation

Davis and Westrum[1] measured directly the enthalpy of the decomposition reaction $KHF_2(cr) \rightarrow KF(cr) + HF(g)$ in an adiabatic calorimeter as $\Delta_{dcm}H° = 18.52 \pm 0.05\ kcal \cdot mol^{-1}$ at 500 K. Reducing to 298.15 K, we obtain $\Delta_{dcm}H°(298.15\ K) = 21.533 \pm 0.05\ kcal \cdot mol^{-1}$ which leads to the enthalpy of formation, $\Delta_f H°(KHF_2, cr, 298.15\ K) = -222.57 \pm 0.3\ kcal \cdot mol^{-1}$, using JANAF auxiliary data. This value is adopted in the tabulation.

Westrum and Pitzer[3] measured the dissociation vapor pressures of KHF_2 (cr, l) by a static method. Their pressure data have been analyzed by both 2nd law and 3rd law methods as given below. The enthalpy of formation derived from the 3rd law analysis differs by about 0.3 $kcal \cdot mol^{-1}$ from the value adopted, which is greater than the combined experimental errors.

Reaction	T/K	Data Points	$\Delta_{dcm}H°(298.15\ K)$, $kcal \cdot mol^{-1}$ 2nd law	3rd law	Drift $cal\ K^{-1} \cdot mol^{-1}$	$\Delta_f H°(298.15\ K)$ $kcal \cdot mol^{-1}$
$KHF_2(cr) \rightarrow KF(cr) + HF(g)$	478–500	14	21.21 ± 0.12	21.31 ± 0.01	0.2 ± 0.2	−222.35
$KHF_2(l) \rightarrow KF(cr) + HF(g)$	504–577	5	19.82 ± 0.08	17.73 ± 0.24	−3.9 ± 0.2	−222.28**

**This value is derived from the adopted heat of melting, $\Delta_{fus}H°(298.15\ K) = 3.504\ kcal \cdot mol^{-1}$ and $\Delta_f H°(KHF_2,l,298.15\ K) = -218.773\ kcal \cdot mol^{-1}$. The latter is calculated from the 3rd law $\Delta_{dcm}H°(298.15\ K)$.

Heat Capacity and Entropy

Westrum and Pitzer[3] measured both low temperature $C_p°$ data (16–315 K) in an adiabatic calorimeter and high temperature enthalpy data (321.6–465 K for α phase and 471.3–505.9 K for β phase) in a drop calorimeter. We use their experimental $C_p°$ data to derive $S°(298.15\ K) = 24.92 \pm 0.1\ cal\ K^{-1} \cdot mol^{-1}$, based on $S° = 0.0643\ cal\ K^{-1} \cdot mol^{-1}$ at 15 K. The low temperature $C_p°$ and high temperature enthalpy data for the α phase are smoothly joined at 298.15 K by a polynomial curve fitting method. The deviations of the observed enthalpy data from the adopted values are 0.68% at 321.6 K and 0.09% at 463.7 K. The constant heat capacity, 23.96 $cal\ K^{-1} \cdot mol^{-1}$, in the β phase is derived from the measured enthalpy data,[3] and is assumed to be the same when the temperature is above the melting point.

Transition and Fusion Data

Davis and Westrum[1] measured the heat of the αβ transition, $\Delta_{trs}H° = 2.682 \pm 0.01\ kcal \cdot mol^{-1}$ at 196.7°C, and the heat of melting, $\Delta_{fus}H° = 1.582 \pm 0.003\ kcal \cdot mol^{-1}$ at 238.8°C in an adiabatic calorimeter. Their data are adopted in the tabulation. Based on the drop calorimetric measurements,[3] we have derived $\Delta_{fus}H° = 1.554\ kcal \cdot mol^{-1}$ which is in good agreement with the value adopted.

$S°(298.15\ K) = [132.764]\ J·K^{-1}·mol^{-1}$ $\Delta_f H°(298.15\ K) = [-916.573]\ kJ·mol^{-1}$
$T_{fus} = 511.95\ K$ $\Delta_{fus}H° = 6.619 \pm 0.013\ kJ·mol^{-1}$

Enthalpy of Formation

The enthalpy of formation is calculated from that of the crystal by adding the enthalpy of fusion, $\Delta_{fus}H°$, and the difference in enthalpy, $H°(511.95\ K)–H°(298.15\ K)$, between the crystal and liquid.

Heat Capacity and Entropy

Westrum and Pitzer[1] measured high temperature enthalpy data by drop calorimetry in a narrow range of 510.6–523.2 K and derived a constant heat capacity of approximately 25 cal $K^{-1}·mol^{-1}$ which is adopted in the tabulation.

A glass transition is assumed at 314 K. Below 314 K, the heat capacities are assumed to be the same as those of the crystal. Between 314 K and the melting point, the $C_p°$ is assumed to be the same as that of the liquid.

The entropy is calculated in a manner similar to that used for the enthalpy of formation.

Fusion Data

Refer to the crystal table for details.

Decomposition Data

The decomposition temperature, $T_{dcm} = 750$ K, is calculated as the temperature at which $\Delta_f G = 0$ for $KHF_2(l) \rightarrow KF(cr) + HF(g)$. At T_{dcm}, the vapor pressure of HF(g) reaches one atmosphere.

Westrum and Pitzer[1] determined the decomposition vapor pressures of KHF_2(cr, l) by a static method. Their data lead to the decomposition temperature, 700 K when the pressure of HF reaches one atmosphere. JANAF analyses of their data are given in KHF_2(cr) table. Their data over the crystal phase are suspected to be high by approximately 11.5%; and the data over the liquid phase are probably in error as indicated by the 3rd law drift (3.9 cal $K^{-1}·mol^{-1}$) in the JANAF analyses.

Enthalpy of Formation

The enthalpy of 2 HF(g) → H_2F_2(g) was taken as the mean of the 3rd law values which were obtained from the following equilibrium data. Briegleb and Strohmeier[1] measured the vapor density of associated HF(g) between 26 and 56°C and between 30 and 700 torr. Franck and Meyer[2] measured the heat capacity between 20 and 100°C and between 100 and 700 torr. Their 2nd law values differed by 1.2 kcal·mol^{-1}; and using the molecular constants discussed below gave respectively mean 3rd law values which differed by 0.34 kcal·mol^{-1}, a 0.14 kcal·mol^{-1} temperature trend for Briegleb and Strohmeier,[1] and a 0.02 kcal·mol^{-1} temperature trend for Franck and Meyer.[2] $\Delta_f H°(H_2F_2, g, 298.15\ K)$ was calculated using auxiliary JANAF data.[3]

Heat Capacity and Entropy

The structure of the semi rigid hydrogen bonded dimer is taken from Dyke *et al.*[4] Using bond distances and angles given by these authors we obtain $I_A = 0.1203 \times 10^{-39}$, $I_B = 12.7869 \times 10^{-39}$, and $I_C = 12.9022 \times 10^{-39}$ ·cm^2. Dyke *et al.*[4] observed a doubling of the rotational energy levels of the dimer and attributed this to a tunneling motion involving breaking of the hydrogen bond, interchange of the two HF units, and formation of a new hydrogen bond. Thus there are two identical configurations for the dimer separated by a low energy barrier so that quantum mechanical tunneling occurs at a significant rate. Therefore the overall symmetry number is 2 even though the external symmetry number is 1.

Reliable experimental values of the vibrational frequencies of H_2F_2(g) are not available. The estimated frequencies are similar to those used for the higher polymers which were obtained from data on HF solid. The infrared absorption bands observed in the vapor (350 to 400 cm^{-1}, 700 to 800 cm^{-1}, and 1000–1200 cm^{-1} regions) are largely due to the higher polymers, such as the tetramer and hexamer. Calculated values (610, 443, and 144 cm^{-1}) were obtained from force constants given in a paper on theory of molecular interactions of the HF polymers by Del Bene and Pople.[5] The potential energy surface computed for the dimer suggests very anharmonic low frequency motions for the external hydrogen (estimated at 600 ± 200 cm^{-1}) and for the hydrogen bond stretching mode.

The National Bureau of Standards prepared this table[6] by critical analysis of data existing in 1972. Using our $I_A I_B I_C$ with other molecular constants and $\Delta_f H°$ selected by NBS,[6] we recalculate the table in terms of 1973 fundamental constants,[7] 1975 atomic weights[8] and current JANAF reference states for the elements.

Ground State Quantum Weight: [1] $\sigma = 2$

Point Group: C_{2v}

Bond Distances: Si–H = 1.471 Å; Si–F = 1.5767 Å

Bond Angles: H–Si–H = 112.02°; F–Si–F = 107.93°

Product of the Moments of Inertia: $I_A I_B I_C = 4.815754 \times 10^{-115}\ g^3 \cdot cm^6$

Enthalpy of Formation

There are no reported experimental studies leading to the enthalpy of formation of SiH_2F_2(g). We estimate this value via a linear interpolation between the established $\Delta_f H°(298.15\ K)$ values of SiH_4(g) and SiF_4(g).[1] The reasonableness of this approach has been demonstrated by Lapidus *et al.*,[2] Hunt and Sirtl,[3] and Seiter and Sirtl.[4]

Heat Capacity and Entropy

The adopted vibrational frequencies are from the gas phase infrared study of Cradock *et al.*[6] Two frequencies (ν_5 and ν_6) were quite uncertain and were discussed in terms of a strong Coriolis interaction.

These frequencies appear quite reasonable when a comparison of the dihalosilanes and dihalomethanes (halogen is fluorine, chlorine, and bromine) is made.[1,5]

The adopted bond distances and bond angles are obtained from the microwave spectrum study by Laurie.[7] The individual moments of inertia are: $I_A = 3.4021 \times 10^{-39}$, $I_B = 10.7552 \times 10^{-39}$, and $I_C = 13.1614 \times 10^{-39}\ g \cdot cm^2$.

$S°(298.15\ K) = [116.315 \pm 8.4]\ J \cdot K^{-1} \cdot mol^{-1}$ $\Delta_f H°(298.15\ K) = [-422.584 \pm 41.8]\ kJ \cdot mol^{-1}$

$T_{fus} = 918\ K$ $\Delta_{fus} H° = [23.012 \pm 4.2]\ kJ \cdot mol^{-1}$

Enthalpy of Formation

Estimated by comparison of the mercurous and mercuric halides.

Heat Capacity and Entropy

The heat capacity is assumed to be a linear function of temperature and was estimated to be 7.0 cal $K^{-1} \cdot g\text{-atom}^{-1}$ at the melting point. The entropy is estimated by comparison with the other mercuric and mercurous halides and use of additive entropy constants for the halogens.[1]

Fusion Data

T_{fus} was given by Ruff and Bahlau.[2] The heat of melting was from Brewer.[3]

Mercury Fluoride (HgF_2) LIQUID $M_r = 238.586806$

$S°(298.15\ K) = [134.246]\ J·K^{-1}·mol^{-1}$
$T_{fus} = 918\ K$

$\Delta_f H°(298.15\ K) = [-404.897]\ kJ·mol^{-1}$
$\Delta_{fus}H° = [23.012 \pm 4.2]\ kJ·mol^{-1}$

Enthalpy of Formation

$\Delta_f H°(HgF_2, l, 298.15\ K)$ is calculated from $\Delta_f H°(HgF_2, cr, 298.15\ K)$ by adding the enthalpy of fusion, $\Delta_{fus}H°$, and the difference in enthalpy, $H°(918\ K)\ H°(298.15\ K)$, between the crystal and liquid.

Heat Capacity and Entropy

$C_p°$ is estimated by analogy with mercuric iodide and bromide. A glass type transitiion is assumed at 613 K below which the heat capacity is that of HgF_2(cr). The entropy is calculated in a manner analogous to that used for the enthalpy of formation.

Fusion and Vaporization Data

T_{fus} was given by Ruff and Bahlan.[1] $T_{vap} = 920\ K$, $\Delta_{fus}H° = 23.0 \pm 4.2\ kJ·mol^{-1}$, and $\Delta_{vap}H° = 92.0 \pm 16.7\ kJ·mol^{-1}$ were all taken from Brewer.[2]

Mercury Fluoride (HgF_2) IDEAL GAS $M_r = 238.586806$

$S°(298.15\ K) = 271.737\ J·K^{-1}·mol^{-1}$

$\Delta_f H°(0\ K) = -288.672\ kJ·mol^{-1}$

$\Delta_f H°(298.15\ K) = [-293.654 \pm 41.8]\ kJ·mol^{-1}$

Vibrational Frequencies and Degeneracies ν, cm^{-1}
[600](1)
[120](2)
[593](1)

Ground State Quantum Weight: 1 $\sigma = 2$

Point Group: $D_{\infty h}$

Bond Distance: Hg–F = [1.96] Å

Bond Angle: F–Hg–F = [180°]

Rotational Constant: $B_0 = [0.115488]\ cm^{-1}$

Enthalpy of Formation

Estimated by comparison with the other gaseous mercuric halides and with the crystalline mercurous mercuric fluorides.

Heat Capacity and Entropy

Vibrational constants were estimated by analogy with the other mercuric halides and the mercurous halides. The bond length was estimated by assuming the mercurous bond to be 0.965 of the mercuric bond by analogy with the mercury chlorides.

PREVIOUS: December 1961 (1 atm) CURRENT: December 1961 (1 bar)

$\Delta_f H°(0\ K)$ = unknown

$S°(298.15\ K)$ = [160.666 ± 8.4] $J·K^{-1}·mol^{-1}$

$\Delta_f H°(298.15\ K)$ = [−485.344 ± 12.6] $kJ·mol^{-1}$

Enthalpy of Formation

A value of $\Delta_f G°(298.15\ K)$ was obtained from the cell measurements of Koerber and de Vries.[1] This was combined with $\Delta_f S°$ from the estimated entropy.

Heat Capacity and Entropy

The heat capacity is estimated by comparison with mercurous chloride. The entropy is estimated by comparison with the other mercurous and mercuric halides and use of additive entropy constants for the halogens from Kelley.[2]

Sublimation Data

Sublimation with decomposition to Hg(g) and HgF_2(g) is assumed at 949 K from the Gibbs energy change of the reaction.

Rotational Constant: $B_0 = [0.094216]\ cm^{-1}$

Enthalpy of Formation

The enthalpy of formation is estimated from three calculated values. The methods of calculation are described as follows. In a manner analogous to $LiF_2^-(g)$, the first reaction considered is $KF(g) + F^-(g) = KF_2^-(g)$ and the $\Delta_f H°(298.15\ K)$ value is evaluated to be between 0 and $1/2(-50) = 25\ kcal·mol^{-1}$ (see $LiF_2^-(g)$ table for details), yielding $\Delta_f H°(KF_2^-, g, 298.15\ K)$ between -140 and $-165\ kcal·mol^{-1}$. The $\Delta_f H°(298.15\ K)$ values for the other species involved are taken from JANAF tables.

The second reaction employed for estimation is $K_2F_2(g) = KF_2^-(g) + K^+(g)$. The enthalpy change of this reaction is calculated as $\Delta_r H°(298.15\ K) = (1/2)(50.0) + 138.8 = 163.8\ kcal·mol^{-1}$ where the KF_2^- ion is considered to be converted from $K_2F_2(g)$ by breaking one of the two dimer association bonds, $\Delta_r H°(298.15\ K) = 50.0\ kcal·mol^{-1}$, and one K^+–F^- ionic bond, $\Delta_r H°(298.15\ K) = 138.8\ kcal·mol^{-1}$. Using $\Delta_f H°(298.15\ K) = -206.2$ and $122.9\ kcal·mol^{-1}$ for $K_2F_2(g)$ and $K^+(g)$, we obtain the enthalpy of formation for $KF_2^-(g)$ as $-165\ kcal·mol^{-1}$.

Based on an assumption that the electron affinity of $KF_2(g)$ is similar to that of F (refer to $LiF_2^-(g)$ table for details), i.e., $\Delta_r H°(298.15\ K) = 83.5\ kcal·mol^{-1}$ for the reaction $KF_2^-(g) = KF_2(g) + e^-(g)$, we derive $\Delta_f H°(KF_2^-, g, 298.15\ K) = -167.7\ kcal·mol^{-1}$. The $\Delta_f H°(KF_2, g, 298.15\ K)$ is calculated as $-84.2\ kcal·mol^{-1}$ from the value $\Delta_r H°(298.15\ K) = 143.3\ kcal·mol^{-1}$ for the reaction $K_2F_2(g) = KF_2(g) + K(g)$ where the $\Delta_r H°(298.15\ K)$ value is calculated as the sum of two enthalpy changes, i.e. half of the heat of dimer dissociation into two monomers or $1/2(50.0) = 25.0\ kcal·mol^{-1}$, and the heat of dissociation of KF(g) or $118.3\ kcal·mol^{-1}$.

The value of $\Delta_f H°(KF_2^-\ 298.15\ K)$ is tentatively adopted as $-166 \pm 10\ kcal·mol^{-1}$.

Heat Capacity and Entropy

The molecular structure is assumed to be linear, according to the suggestion given by Walsh[2] that molecules with not more than 16 valency electrons are linear in their ground states. The K–F bond distance is taken to be the same as that of KF(g) reported by Veazey and Gordy.[3] The vibrational frequencies are estimated from the vibrational frequency of KF(g) using the method suggested by Herzberg.[4]

Bond Distance: K–F = 2.2 Å
Bond Angles: F–K–F = [90°]: K–F–K = [90°]
Product of the Moments of Inertia: $I_A I_B I_C = [2.240426 \times 10^{-113}]\ g^3 \cdot cm^6$

Enthalpy of Formation

The equilibrium constants (K_c) for the reaction $K_2F_2(g) = 2\ KF(g)$, in the temperature range 974–1052 K, were determined by Eisenstadt *et al.*[1] Although the reported absolute values of the vapor pressures of KF(cr) are not adopted for evaluation, the reported K_c values are used to calculate the enthalpy change, $\Delta_r H°(298.15\ K)$, for the above reaction. The 2nd and 3rd law values of $\Delta_r H°(298.15\ K)$ are derived as 51.0 ± 1.6 and 50.0 $kcal \cdot mol^{-1}$, respectively. Based on the 3rd law $\Delta_r H°(298.15\ K)$ and $\Delta_f H°(KF, g, 298.15\ K) = -78.1\ kcal \cdot mol^{-1}$, we obtain $\Delta_f H°(298.15\ K) = -206.2\ kcal \cdot mol^{-1}$ ($-862.74 \pm 8.4\ kJ \cdot mol^{-1}$) for $K_2F_2(g)$ which is tentatively adopted.

Heat Capacity and Enthalpy

The molecular structure and K–F bond distance were determined by Akishin and Rambidi,[2] using electron diffraction with sector microphotometry. The bond angles are estimated by comparison with other alkali halide dimers. The vibrational frequencies are taken from Berkowitz[3] which were calculated based on an ionic model. The three principal moments of inertia are: $I_A = 15.2693 \times 10^{-39}$, $I_B = 31.4238 \times 10^{-39}$, and $I_C = 46.6931 \times 10^{-39}\ g \cdot cm^2$.

Enthalpy of Formation

Due to lack of thermal data, the enthalpy of formation for LiF_2^- (g) is arbitrarily selected from the following three estimated values. For the reaction (1) LiF(g) + F^-(g) = LiF_2(g), we expect the enthalpy change would be between 0 to −31 K cal·mol^{-1}. Comparison with the other molecules like CO_2, BOF, BeF_2, etc. having 16 valence electrons leads us to assume that the isoelectronic molecule LiF_2^- should also be quite stable. This indicates that reaction (1) is favorable or $\Delta_r H°(298.15\ K)$ is negative. However, the LiF–F^- bond strength is expected to be weaker than half of the two ionic bonds between Li^+ and F^- in Li_2F_2 molecule (refer to Li_2F_2(g) table for the molecular structure). In other words, the $\Delta_r H°(298.15\ K)$ value of reaction (1) is less negative than half of the enthalpy of dimerization (−62.4 K cal·mol^{-1}). Incorporating $\Delta_r H°(298.15\ K) = 0$ and −31 K cal·mol^{-1}, respectively, for reaction (1), with $\Delta_f H°(298.15\ K) = -81.45$ and −62.2 kcal·mol^{-1} for LiF(g) and F^- (g), we derived the corresponding values for $\Delta_f H°(LiF_2^-, g, 298.15\ K)$ as −144 and −175 K cal·mol^{-1}, which are the upper and lower limits.

The electron affinities of Li and F atoms are reported as 0.7 and 3.448 eV, respectively, by Beckett and Cassidy.[1] From this data we estimate that the electron affinity of LiF_2(g) should be closer to that of F atom than to that of Li. Assuming $\Delta_r H°(298.15\ K)$ = electron affinity of F atom = 83.5 kcal·mol^{-1} for the reaction LiF_2^- (g) = LiF_2(g) + e^- (g), we obtain the enthalpy of formation for LiF_2^- (g) as 177.3 kcal·mol^{-1}. The $\Delta_f H°(LiF_2, g, 298.15\ K)$ used for calculation is derived from an estimated $\Delta_r H°(298.15\ K) = 169.9$ kcal·mol^{-1} for the decomposition of LiF dimer of Li_2F_2(g) = LiF_2(g) + Li(g) as the sum of two enthalpy changes, namely, half of the enthalpy of dissociation of the dimer and the enthalpy of dissociation of the monomer.

The third estimated value for the enthalpy of formation of LiF_2^- (g) is calculated as follows. Based on the two enthalpies of reaction, i.e. $\Delta_r H°(298.15\ K) = 62.4$ kcal·mol^{-1} for Li_2F_2(g) = LiF(g), and $\Delta_r H°(298.15\ K) = 183.5$ kcal·mol^{-1} for LiF(g) = Li^+(g) + F^- (g), we assume the enthalpy change of the reaction Li_2F_2(g) = LiF_2^- (g) + Li^+(g) to be 1/2(62.4) + 183.5 = 214.7 kcal·mol^{-1}. In other words, we consider the LiF_2^- (g) molecule is formed by breaking half of the dimer dissociation bonds and one monomer dissociation bond to produce two ions. Using $\Delta_f H°(298.15\ K) = -225.33$ and 164.24 K cal·mol^{-1} for Li_2F_2(g) and Li^+(g), we evaluate $\Delta_f H°(LiF_2^-, g, 298.15\ K) = -174.9$ kcal·mol^{-1}.

From the above three estimated values, we tentatively choose $\Delta_f H°(LiF_2^-, g, 298.15\ K)$ as -170 ± 15 K cal·mol^{-1}.

Heat Capacity and Entropy

According to Walsh,[3] molecules with not more than 16 valence electrons are linear in their ground states. Since LiF_2^- (g) has 16 valence electrons, we assume its molecular structure is linear. The Li–F bond distance is estimated by comparison with that of LiF(g) reported by Wharton *et al.*[2] The vibrational frequencies are estimated from those of the isoelectronic gaseous molecules, CO_2 and BeF_2.

Enthalpy of Formation

$\Delta_f H°(Li_2F_2, g, 298.15\ K)$ is calculated based on the adopted value $\Delta_f H°(1000) = 61.4\ kcal \cdot mol^{-1}$ for the reaction $Li_2F_2(g) = 2LiF(g)$ which is consistent with the literature values listed in the table below. Due to lack of Knowledge of the fragmentation patterns, the relative ionization cross sections of the ionic species formed in the mass spectrometer, and the molecular constants of the LiF polymers, the evaluation of equilibrium constants used to calculate $\Delta_f H°$ involves considerable uncertainty. In order to solve this problem more research work seems necessary.

*derived from reported vapor pressures of LiF(g) and Li_2F_2(g) at 1073 K.

Heat Capacity and Entropy

The molecular structure of Li_2F_2(g) was determined as D_{2h} by Bushler *et al.*,[12] using electric deflection and mass spectrometric detection. Akishin and Rambidi[7] studied the structure of Li_2F_2(g) by electron deflection with sector microphotometry and assigned the bond distances of Li–F and F–F which are adopted. Evidence for a matrix stabilized linear structure of Li_2F_2 has been obtained by extending the spectral measurements for matrix isolated lithium fluoride into the far infrared region by Redington[8] and Abramowitz *et al.*[9]

Klemperer and Norris[10] observed two infrared active vibrational frequencies, 640 and 460 cm^{-1}, and assigned them as $\nu_5(B_{2u})$ and $\nu_6(B_{3u})$ The infrared absorption spectra of lithium fluoride monomer and dimer isolated in solid inert gas matrices were investigated by Linevsky,[11] Snelson and Pitzer,[13] and Schlick and Schnepp.[14] Redington[8] obtained infrared spectra of LiF species suspended in solid Ne, O_2, CO, and CH_4 at liquid helium temperature. The observed solvent shifts for LiF and Li_2F_2 spectra exhibit several regularities. The vibrational frequencies used for calculation are those reported by Snelson[1] who re–examined the spectrum of LiF species over the range 200–4000 cm^{-1}, using sample purity of 99.3%. The saturated vapor was isolated at 900°C and the superheated unsaturated vapor at 1200°C. A variety of deposition rates and matrix dilutions was tried. Based on the frequencies assigned to the isotopic species, the vibrational frequencies of the natural isotopic Li_2F_2(g) are calculated. It appears that the vibrational frequencies calculated on the basis of the potential function for an ionic model by Berkowitz[1] are too low.

The three principal moments of inertia are: $I_A = 2.3980 \times 10^{-39}$, $I_B = 11.2447 \times 10^{-39}$ and $I_C = 13.6427 \times 10^{-39}\ g \cdot cm^2$.

$S°(298.15\ K) = 57.255 \pm 0.21\ J \cdot K^{-1} \cdot mol^{-1}$
$T_{fus} = 1536 \pm 5\ K$

$\Delta_f H°(0\ K) = -1120.332 \pm 1.3\ kJ \cdot mol^{-1}$
$\Delta_f H°(298.15\ K) = -1124.241 \pm 1.3\ kJ \cdot mol^{-1}$
$\Delta_{fus} H° = 58.702 \pm 0.4\ kJ \cdot mol^{-1}$

Enthalpy of Formation

Rudzitis *et al.*[1] used fluorine bomb calorimetry to study the heat of combustion of a highly pure (99.91 mole %) sample of magnesium. Six combustion experiments were performed, and the sole combustion product was identified as MgF_2 by x-ray diffraction. Values for the completeness of combustion ranged from 98.4 to 99.99%. Corrections for the unburned magnesium were based on analysis performed by hydrogen evolution. This study gave $\Delta_f H°(MgF_2, cr, 298.15\ K) = -268.7 \pm 0.3\ kcal \cdot mol^{-1} (-1124.241 \pm 1.3\ kJ \cdot mol^{-1})$ which is adopted. The quoted uncertainty is twice the combined standard deviation arising from the scatter in the six results and from the analytical and calibration data.

More uncertain values for $\Delta_f H°$ derived indirectly from reaction calorimetry,[2,3] high temperature equilibria,[4] and emf's of solid electrolyte galvanic cells[5,6] are tabulated below. The original data are reanalyzed with the use of the most recent auxiliary data. These sources are included in the table.

[a] 3rd Law Values
[b] $\Delta_f H°$(HF, aq) consistent with JANAF value for HF(g); also, ϕ_c(HF, aq) taken from reference 9.

Auxiliary $\Delta_f H°(298.15\ K)$ values (kcal·mol^{-1}): $Mg(OH)_2$(cr), −221.0 ± 0.5;[7] HF4.5 H_2O, −76.6 ± 0.1;[c] H_2O(l), −68.315;[8] $HF8OH_2O$, −76.8 ± 0.1;[c] H_2O(g), −57.7979;[7] MgO(cr), −143.7 + 0.15;[7] HF(g), −65.14 ± 0.2;[7] AlF_3(cr), −361.0 ± 0.3[7] With the exception of the older calorimetric measurements of Wartenberg,[3] these results are in reasonable agreement with the directly measured $\Delta_f H°$ value.[1]

Heat Capacity and Entropy

Todd[10] measured the low temperature heat capacities (54.2−296.5 K) by adiabatic calorimetry. These $C_p°$ data extrapolate to 14.71 cal·K^{-1}·mol^{-1} at 298.15 K. Integration of these $C_p°$'s gives $S°(298.15\ K) = 13.68$ cal K^{-1}·mol^{-1} when combined with $S°(51\ K) = 0.539$ cal·K^{-1}·mol^{-1}. The latter value is calculated from a combination of Debye and Einstein functions which fits all the experimental $C_p°$ data with an average deviation of ±1.0%.

Relative enthalpies $H°(T;298.15)$ have been measured (411.3−1516 K) by the "drop" method[11] on a portion of the same sample used for the $C_p°$ study.[10] Gravimetric analysis for Mg as $MgSO_4$ indicated a MgF_2 purity of 99.87 wt%. However, premelting effects which appear in the experimental enthalpies about 80° below the melting point suggest that the sample was probably somewhat less pure. Insufficient information is reported to attempt to correct for the impurities. High temperature heat capacities (300–2000 K) are derived from the measured enthalpies[11] by curve fitting with orthogonal polynomials. The curve is constrained to join smoothly with the low-temperature $C_p°$ data near 298.15 K. Three enthalpy points which appear to involve premelting are not included in the fit. Also, we omit the enthalpy point at 411.3 K which shows an usually large positive deviation (+2.9%) from the adopted curve. The maximum deviation of the seven enthalpy points used in the fit is −0.5% and occurs at 1032.7 K. The older heat capacity measurements (288–1278 K) reported by Krestovnikov and Karentnikov[12] are considered less reliable and are not included in our evaluation.

Fusion Data

T_{fus} is the value measured by drop calorimetry.[11] Melting point determinations (1529 and 1534 K) on two commercially available materials which had been further purified by hydrofluorination[13] suggest an uncertainty in the adopted T_{fus} value (1536 K) of ±5 K. Other literature values include 1525 K[14] and 1528 K.[15]

$\Delta_{fus} H°$ is calculated as the difference between JANAF enthalpies for the liquid and crystal at T_{fus}. Other reported values for $\Delta_{fus} H°$ are 13.9[11] and 13.15 kcal·mol^{-1}.[14]

Sublimation Data

Refer to the ideal gas table for details.

PREVIOUS: March 1966 CURRENT: June 1975

$S°(298.15\ K) = [89.967]\ J·K^{-1}·mol^{-1}$ $\Delta_fH°(298.15\ K) = [-1072.356]\ kJ·mol^{-1}$
$T_{fus} = 1536 \pm 5\ K$ $\Delta_{fus}H° = 8.702 \pm 0.4\ kJ·mol^{-1}$

Enthalpy of Formation

$\Delta_fH°(MgF_2, l, 298.15\ K)$ is calculated from $\Delta_fH°(MgF_2, cr, 298.15\ K)$ by adding the enthalpy of fusion, $\Delta_{fus}H°$, and the difference in enthalpy, $H°(1536\ K)-H°(298.15\ K)$, between the crystal and liquid.

Heat Capacity and Entropy

Naylor[1] has measured relative enthalpies (1539–1760 K) for the liquid by drop calorimetry. These results give a $C_p°(l)$ equal to 22.687 $cal\ K^{-1}·mol^{-1}$. This value is used in the temperature range 1000–3000 K. Below 1000 K, the assumed glass transition temperature, $C_p°$ is assumed to be that of the crystal. $S°(298.15\ K)$ is calculated in a manner analogous to that used for the enthalpy of formation.

Fusion Data

Refer to the crystal table for details.

Vaporization Data

T_{vap} = 2536 K is the temperature at which $\Delta_rG°$ for the process MgF (l) = MgF_2 (g) is zero. $\Delta_{vap}H° = 274.052\ kJ·mol^{-1}$ is the difference between the $\Delta_fH°$ values for the gas and liquid at T_{vap}. Several methods[2-6] predict an insignificant amount of dimer (–1%) in the saturated vapor below 2000 K.

508 (1)	215 (1)	875 (1)

Ground State Quantum Weight: [1] $\sigma = 2$

Point Group: C_{2v}

Bond Distance: Mg–F = 1.77 ± 0.02 Å

Bond Angle: F–Mg–F = 158°

Product of the Principal Moments of Inertia: $I_A I_B I_C = 1.033673 \times 10^{-115}\ g^3 \cdot cm^6$

Enthalpy of Formation

$\Delta_{sub}H°(298.15\ K)$ is added to $\Delta_f H°(MgF_2, cr, 298.15\ K)$ to give $\Delta_f H°(g, 298.15\ K) = 173.7 \pm 0.8\ kcal \cdot mol^{-1}$. $\Delta_{sub}H°(298.15\ K)$ is selected from the results of a 3rd law analysis of twenty sets[19] of vapor pressure data for MgF_2(cr, l). These measurements cover an extended temperature range (~1200°) and include the use of manometric,[1, 4] Knudsen effusion,[2, 5, 6] torsion effusion[5–8] and mass spectrometric[3, 9] methods. The amount of dimer present in the saturated vapor is predicted not to exceed 1% below 2000 K by several methods.[3, 6, 7–9]

Reactions: (A) $MgF_2(l) = Mg + F_2(g)$; (B) $MgF_2(cr) = MgF_2(g)$.

[a]2nd law value by slope method. [b]One point rejected due to failure of a statistical test.

[c]Two points rejected due to failure of a statistical test.

These data are in agreement on $\Delta_{sub}H°(298.15\ K) = 95.0 \pm 0.5\ kcal \cdot mol^{-1}$. We adopt this value but assign an alternate uncertainty to $\Delta_f H°$ to include the possibility that MgF_2 is linear (refer below).

Heat Capacity and Entropy

Considerable confusion exists as to whether MgF_2 is bent or linear. Electron diffraction,[11] electric deflection,[12] matrix isolation Raman[23] and infrared[13, 22, 23] spectral studies, and MO calculations[14–16, 24] predict a linear configuration. Other matrix isolation IR studies[17, 18] and MO calculations[19, 24] favor the nonlinear structure. Isotopic shifts[18] in the matrix frequencies suggest that the most probable value of the apex angle

Enthalpy of Formation

The MgF_2^+ ion has been identified as an important species in the vapor mass spectra of the MgF_2,[1-3] MgF_2–Tl–Pd[4] and MgF_2–Cu[5] systems. The observed appearance potentials (AP) for this ion are tabulated below.

Source	Year	AP, eV
Berkowitz and Marquart[1]	1962	13.5±0.4
Green *et al.*[2]	1964	13.6
Murad *et al.*[4]	1966	14.0±0.5
Hildenbrand[5]	1968	13.5
Hildenbrand[3]	1968	13.3±0.3

These results show the normal scatter expected for such measurements; the largest deviation is 0.7 eV. We adopt an average value of 13.6±0.2 eV (313.62±4.6 $kcal \cdot mol^{-1}$), and we assume that this value refers to the direct ionization process $MgF_2(g) + e^- = MgF_2^+(g) + 2e^-$ occurring at 0 K. Combining the selected AP value with $\Delta_f H°(MgF_2, g) = -173.3 \pm 0.8\ kcal \cdot mol^{-1}$,[6] we obtain $\Delta_f H°(MgF_2^+, g, 0\ K) = 140.3 \pm 5\ kcal \cdot mol^{-1}$. The $\Delta_f H°$ value at 298.15 K is 141.5 $kcal \cdot mol^{-1}$. An alternate uncertainty of $\pm 9\ kcal \cdot mol^{-1}$ is included to cover the possibility that the MgF_2 molecule is linear.[6]

Heat Capacity and Entropy

A comparison of the atomization energies, $\Delta_{at} H°(0\ K)$ in $kcal \cdot mol^{-1}$, for MgF_2(245)[6] and MgF_2^+ (107.7) suggests weaker bonding in the ion relative to the neutral molecule. One might therefore expect that the fundamental frequencies of MgF_2^+ would be somewhat less than those for MgF_2. We assume a slight decrease in the three vibrational frequencies of MgF_2.[6] MgF_2^+ (fifteen valence electrons) is isoelectronic with the molecules BO_2, N_3, NCO, and N_2O^+. By analogy with the ground states[6] for these isoelectronic molecules, we assume that the ground state for MgF_2^+ is $^2\Pi$. We also include two excited states ($^2\Pi$ and $^2\Sigma$) which would be expected to exist based on those observed for BO_2.[6]

According to the diagram of Walsh,[7] MgF_2^+ is predicted to be linear. This prediction is supported by the fact that several other fifteen valence electron molecules (BO_2, NCO, N_2O^+, and N_3) are now known to be linear in their ground states. We adopt a linear configuration. Due to the weaker bonding in MgF_2^+ relative to MgF_2, it is reasonable to assume that $r_e(MgF_2^+) > r_e(MgF_2)$. We assume a 10% increase in the bond length for MgF_2.[6]

Enthalpy of Formation

The adopted enthalpy of formation at 298.15 K is that derived by Brewer[1] from the high temperature mass spectrometric measurements of equilibria among gaseous fluorides by Hildenbrand (1818–2242 K).[2] The value of $\Delta_fH°(0\ K)$ combined with JANAF data[3] for Mo(g) and F(g) gives $\Delta_{at}H°(0\ K) = 232.8 \pm 6\ kcal \cdot mol^{-1}$ and an average Mo–F bond energy of $\Delta_{at}H°(0\ K)/2 = 116.4 \pm 3\ kcal \cdot mol^{-1}$.

Heat Capacity and Entropy

We use the vibrational frequencies of 700(2) and 150(2) cm^{-1} estimated by Hildenbrand[2] and adopted by Brewer.[1] Brewer[1] assumed a linear molecule with a Mo–F distance of 1.82 Å as in MoF_6(g). No electronic level data are available for the dihalides of molybdenum. Brewer[1] uses g = 3 for the ground state and one excited level at 450 cm^{-1} with g = 5. Additional electronic contributions are expected, but the electronic contribution was kept small[1] to be as consistent as possible with the smaller entropy values derived for MoF(g) and MoF_2(g) from the 2nd law treatment of Hildenbrand's equilibria data.[2]

This table is based on the critical analysis of data existing in 1978 by Brewer.[1]

Enthalpy of Formation

Colburn and Johnson[1] reported the study of the dissociation reaction $N_2F_4(g) = 2\ NF_2(l)$ by two independent methods: (a) measurement of the pressure variation with temperature at constant volume and (b) a spectrophotometric method based on the temperature dependence of the ultraviolet absorption of NF_2 radical. The authors gave a more detailed account of their data in a later publication.[2] The contents of these articles indicate that 2 $NF_2(l)$ should read 2 $NF_2(g)$ in the above reaction. The first method gave a value of 19.85 $kcal·mol^{-1}$ for the enthalpy of dissociation in the temperature range 373 to 423 K which corresponds to 19.87 $kcal·mol^{-1}$ at 298.15 K. From their ΔH and ΔS data, ΔG was calculated and used in a 3rd law evaluation of the enthalpy of dissociation. The $\Delta_f H°(298.15\ K)$ so calculated showed an increasing trend with increasing temperature; the average value was 22.87 $kcal·mol^{-1}$ which is not in agreement with their value of 19.87 $kcal·mol^{-1}$. The spectrophotometric value of 21.7 $kcal·mol^{-1}$ at 298.15 K was obtained from the integrated Van't Hoff equation.

Piette, Johnson, Booman and Colburn[3] studied the temperature dependence of the EPR spectrum of the NF_2 radical. They obtained a 2nd law value of 19.3 $kcal·mol^{-1}$ for the enthalpy of dissociation. This value, however, depends upon the degree of dissociation of N_2F_4 which they calculated from the (dP/dT) measurements of Colburn and Johnson.[1] Any error in the (dP/dT) measurements would manifest itself in like manner here.

Doorenbos and Loy[4] investigated the ESR spectrum of the N_2F_4–NF_2 equilibrium from which they calculated a 2nd law value of 19.8 $kcal·mol^{-1}$ for the enthalpy of dissociation. They report that at 25°C and 13 atm, N_2F_4 is 0.022% dissociated in the vapor phase. A 3rd law calculation using this datum and the relationship $K_p = (4\alpha^2/1-\alpha^2)P_T$, where α is the degree of dissociation of N_2F_4 and P_T is the total pressure, gave a heat of dissociation of 21.79 $kcal·mol^{-1}$ at 298.15 K; this is not in agreement with their 2nd law value.

Herron and Diebler[5] report thermal dissociation data for N_2F_4. From their data they calculated a 2nd law value of 21.5 $kcal·mol^{-1}$ for the heat of dissociation of N_2F_4. A 2nd and 3rd law evaluation of their data was performed. It is found that if the k factor, relating their measured ion abundances to partial pressure, is taken as 4.72×10^{-8}, a 3rd law is obtained that shows slight scatter but no temperature dependence. Excluding those points that showed scatter, the 3rd law heat of dissociation at 298.15 K is 22.27 $kcal·mol^{-1}$. A 2nd law plot gives a heat value of 22.23 $kcal·mol^{-1}$ at an average temperature of 400 K or 22.25 $kcal·mol^{-1}$ at 298.15 K. Those points that deviated from the chosen straight line in the 2nd law plot shows corresponding deviations in the 3rd law calculation. Those points lying on the 2nd law slope give a constant 3rd law value.

The enthalpy of dissociation for $N_2F_4(g) = 2\ NF_2(g)$ is taken to be 22.26 $kcal·mol^{-1}$. Utilizing the enthalpy of formation of $N_2F_4(g)$, the enthalpy of formation of the difluoroamino radical becomes $10.1 \pm 2.0\ kcal·mol^{-1}$. All values for the enthalpy of dissociation fall within the limits of error assigned to the enthalpy of formation of NF_2.

Heat Capacity and Entropy

Refer to table on tetrafluorohydrazine, $N_2F_4(g)$, for discussion.

Ground State Quantum Weight: = 1 $\sigma = 2$

Point Group: C_{2v}

Bond Distances: N–F = 1.384 Å; N–N = 1.214 Å

Bond Angle: F–N–N = 114.5 ± 0.5°

Product of the Moments of Inertia: $I_A I_B I_C = 6.590443 \times 10^{-115}\ g^3·cm^6$

Enthalpy of Formation

The enthalpy of formation was derived from the heat of reaction $N_2F_2(g) + 8/3\ NH_3(g) = 2\ NH_4F(cr) + 4/3\ N_2(g)$ which was measured calorimetrically by Armstrong and Marantz.[1] There are two isomers, the trans and the active form of difluoridiazine. The enthalpy of formation were determined to be 19.4 and 16.4 kcal·mol^{-1} for the trans and the active isomers, respectively. The active form of N_2F_2 has been interpreted here as the cis isomer which will be discussed later. The enthalpy of isomerization has also been reported as 3.0 kcal·mol^{-1} by Armstrong and Marantz. The value, $\Delta_f H°$(cis N_2F_2, g, 298.15 K) = 16.4 kcal·mol^{-1}, is adopted in the tabulation.

Pankratov *et al.*[2] have measured the enthalpy of reaction $N_2F_2(g) + 3\ KI = 2\ KF + N_2 + KI_3$ in acidic solution (pH = 3), and reported $\Delta_f H°$(active N_2F_2, g, 298.15 K) = 25.3 ± 2.0 kcal·mol^{-1}.

The "heat of isomerization" has been reported as 27.5 ± 5.0 kcal·mol^{-1} by Colburn *et al.*[9] The derivation of this value is unknown. The authors observed three values of the equilibrium constant for the isomerization reaction. Third law analysis of their data gives $\Delta_r H°(298.15\ K) = 2.52 \pm 0.05$ kcal·mol^{-1} for the reaction *cis* $N_2F_2(g) \rightarrow$ trans $N_2F_2(g)$ which is in good agreement with Armstrong and Sidney's data.

Heat Capacity and Entropy

Although the infrared spectrum[7,8] of the active form of $N_2F_2(g)$ has been interpreted as favoring the 1,1–di–flurodiazine over the *cis* configuration,[3,4] NMR[5] and microwave[6] studies definitely indicate the latter. The vibrational frequencies[7] previously assigned to the 1,1–difluorodiazine have been adopted here for the *cis* isomer. The selected bond distances and angle were taken from the isotopic nitrogen microwave studies.[6] The principal moments of inertia were: $I_A = 4.2469 \times 10^{-39}$, $I_B = 10.5134 \times 10^{-39}$, and $I_C = 14.7603 \times 10^{-39}$ g·cm^2.

Refer to the trans–N_2F_2(g) table for the comparison of the different physical properties between *trans* and *cis* isomers.

Bond Distances: N–F = 1.44 Å; N–N = 1.25 Å

Bond Angle: F–N–N = 115°

Product of the Moments of Inertia: $I_A I_B I_C = 4.328461 \times 10^{-115}\ g^3·cm^6$

Enthalpy of Formation

Armstrong and Marantz[1] have measured calorimetrically the enthalpy of reaction $N_2F_2(g) + 8/3\ NH_3(g) = 2\ NH_4F(cr) + 4/3\ N_2(g)$, and reported $\Delta_f H°$(*trans* N_2F_2, g, 298.15 K) = 19.4 ± 1.2 kcal·mol^{-1} which is adopted in this tabulation.

Heat Capacity and Entropy

The bond distances and bond angle were obtained from Bauer[2] by electron diffraction. The fundamental vibrational frequencies were obtained from Sanborn[3] by infrared spectroscopy. The three principal moments of inertia are $I_A = 0.9191 \times 10^{-39}$, $I_B = 21.2461 \times 10^{-39}$, and $I_C = 22.1652 \times 10^{-39}\ g·cm^2$.

As pointed out by Ettinger *et al.*,[4] the *trans* N_2F_2 is the less active isomer which is different from the active isomer by its (1) vapor pressure (2) boiling point (3) heat of vaporization (4) critical temperature (5) melting point (6) mass spectral cracking pattern (7) NMR spectrum (8) infrared spectrum (9) heat of isomerization (10) reactivity with mercury and glass.

Enthalpy of Formation

The enthalpy of formation for NaF_2^-(g) is estimated from three calculated values. The methods of calculation are described as follows. The first reaction we take into consideration is NaF(g) + F^-(g) = NaF_2 (g). In a manner analogous to LiF_2 (g) molecule (see LiF_2^-(g) table for details), we assume NaF_2^-(g) is stable and $\Delta_f H°$(298.15 K) for the reaction NaF(g) + F^-(g) = NaF_2^-(g) is somewhere between 0 to 1/2(−64) = −32 kcal·mol^{-1} where the value −56 kcal·mol^{-1} is the enthalpy of dimerization. Based on $\Delta_f H°(298.15\ K) = 0$ and −28 kcal·mol^{-1}, respectively, with JANAF $\Delta_f H°$(298.15 K) values for the species involved, we obtain $\Delta_f H°(NaF_2^-, g, 298.15\ K)$ = −132 and −164 kcal·mol^{-1} as the upper and lower limits.

The enthalpy of formation, based on the reaction $NaF_2^-(g) = NaF_2(g) + e^-(g)$, is −165.8 kcal·$mol^{-1}$, using $\Delta_r H°$(298.15 K) and $\Delta_f H°(NaF_2, g, 298.15\ K)$ estimated as 83.5 and −82.3 kcal·mol^{-1}, respectively. The $\Delta_r H°$(298.15 K) value is obtained from an assumption that the enthalpy change for removing an electron from NaF_2^-(g) is comparable to that from F^-(g). Due to the fact that the Na atom has smaller electronegativity (0.9) than that of the F atom (4.0), we expect that there is less possibility that the electron will associate with Na atom in the NaF_2^- molecule. Therefore, we adopt EA(F,g), reported by Pritchard,[1] or $\Delta_r H°(298.15\ K) = 83.5$ kcal·mol^{-1} for the reaction $F^-(g) = F(g) + e^-(g)$ as the $\Delta_r H°$(298.15 K) for NaF_2^- (g) = NaF_2(g) + e^-(g). The value of $\Delta_f H°$(298.15 K) for NaF_2(g) is calculated using the enthalpy change for the reaction $Na_2F_2(g) = NaF_2(g) + Na(g)$ as 145.8 kcal·mol^{-1} which is derived from the sum of two enthalpy changes, namely, half of the $\Delta_r H°$(298.15 K) value for the dimer dissociation reaction $Na_2F_2(g) = 2NaF(g)$, and the $\Delta_r H°$(298.15 K) for the monomer dissociation reaction NaF(g) = Na(g) + F(g).

Employing $\Delta_r H°(298.15\ K) = 63.5$ kcal·mol^{-1} for $Na_2F_2(g) = 2NaF(g)$ and 153.0 kcal·mol^{-1} for NaF(g) = Na^+(g) + F^-(g), we estimate $\Delta_r H°(298.15\ K) = (1/2)(63.5) + 153.0 = 184.7$ kcal·mol^{-1} for the reaction $Na_2F_2(g) = NaF_2(g) + Na^+(g)$, which leads to $\Delta_f H°(298.15\ K)$ = 163.4 kcal·mol^{-1} for NaF_2 (g). For all calculations the $\Delta_f H°$(298.15 K) values of the chemical species involved are taken from JANAF Thermochemical Tables.

$\Delta_f H°(NaF_2^-, g, 298.15\ K)$ is tentatively adopted as −160±10 kcal·mol^{-1} (−669.440±41.8 kJ·mol^{-1}).

Heat Capacity and Entropy

The molecular structure is assumed to be linear, according to the suggestion by Walsh[2] that molecules with not more than 16 valence electrons are linear in their ground state. The Na–F bond distance is estimated by comparison with that of NaF(g) reported by Veazey and Gordy.[3] The vibrational frequencies are estimated from those for the isoelectronic molecule SiO_2(g).

Enthalpy of Formation

Although the absolute values of the vapor pressure measurements are not used for evaluation, the ratios of the numbers of dimeric and monomeric NaF molecules that effuse from the oven at the temperatures 1115–1191 K determined by Eisenstadt *et al.*[1] by use of the electron beam velocity selector method are used. Based on the reported equilibrium data, we evaluate the enthalpy change of the reaction (A) $Na_2F_2(g) = 2\ NaF(g)$ by the 2nd and 3rd law methods. The results are presented in the table below.

Porter and Schoonmaker[2] analyzed the vapor effusing from a Knudsen cell at 1121 K mass spectrometrically and derived the partial pressures of NaF(g) and $Na_2F_2(g)$ at that temperature. Using these reported partial pressures we calculate, by the 3rd law method, the value $\Delta_f H°(298.15\ K) = 64.1\ kcal\cdot mol^{-1}$ for reaction (A).

Sidorov *et al.*[3] studied the NaF–ZrF_4 system by the mass spectrometric method and derived the partial pressures of NaF(g) and $Na_2F_2(g)$ as a function of composition and temperature. Employing the data points reported at 1074 and 1167 K we obtain the 3rd law value $\Delta_f H°(298.15\ K) = 62.0 \pm 1.6\ kcal\cdot mol^{-1}$ for the same reaction.

The $\Delta_f H°(Na_2F_2, g, 298.15\ K)$ is calculated based on the adopted 3rd law value $\Delta_f H°(298.15\ K) = 63.5\ kcal\cdot mol^{-1}$ for the reaction $Na_2F_2(g) = 2\ NaF(g)$, using $\Delta_f H°(NaF, g, 298.15\ K) = -69.5\ kcal\cdot mol^{-1}$. Brewer and Brackett[9] reported $\Delta_f H°(1000\ K) = 56.9\ kcal\cdot mol^{-1}$ for the above reaction. According to our tables the $\Delta_f H°(1000\ K)$ value is 62.5 $kcal\cdot mol^{-1}$.

Heat Capacity and Entropy

The $Na_2F_2(g)$ molecule is assumed to have a rhombic structure with D_{2h} (ν_h) symmetry.[4,5] The Na–F bond distance is reported by Akishin and Rambidi,[5] who studied the molecular structure of alkali halide vapors by electron diffraction with sector microphotometry. The bond angle is estimated by comparison with those of the other alkali halides. Berkowitz[4,6] has calculated the vibration frequencies of Na_2F_2 based on an ionic model. By comparison of the calculated frequencies of Li_2F_2[6] with those of the observed ones (see Li_2F_2(g) table for details), we re-estimate the vibrational frequencies for $Na_2F_2(g)$ to be higher than the ones reported by Berkowitz.[6] Bauer *et al.*[7] used a pseudo electrostatic model, similar to the one suggested by O'Konski and Higuchi,[8] to calculate the entropies of dimerization for a number of gaseous alkali halides and estimated the six vibrational frequencies as 477, 318, 291, 477, 291 and 291 cm^{-1}. Bauer *et al.*[7] calculated $\Delta_{sub}H°(1146\ K) = -32.5$ $cal\ K^{-1}\cdot mol^{-1}$ for the reaction $2\ NaF(g) = Na_2F_2(g)$, in reasonable agreement with the value $-33.5\ cal\ K^{-1}\cdot mol^{-1}$ which is derived using JANAF $S°(1146\ K)$ values for NaF(g) and $Na_2F_2(g)$.

The three principal moments of inertia are: $I_A = 13.9948 \times 10^{-39}$, $I_B = 14.2197 \times 10^{-39}$, and $I_C = 28.2145 \times 10^{-39}\ g\cdot cm^2$.

Enthalpy of Formation

King and Armstrong[1] have established the enthalpy of formation with a series of reactions in a flame calorimeter. They burned OF_2 in hydrogen to give HF aqueous; in addition they burned F_2 in hydrogen and O_2 in hydrogen so that the enthalpy of formation, 24.52 $kJ \cdot mol^{-1}$, was directly obtainable. This value was in good agreement with the recalculated values of Wartenberg and Klinkott,[2] 23.85 ± 12.6 $kJ \cdot mol^{-1}$, and of Ruff and Menzel,[3] 19.66 ± 8.45 $kJ \cdot mol^{-1}$ but differed from that of Bisbee *et al.*,[4] −16.99 ± 8.4 $kJ \cdot mol^{-1}$. There are several factors in the experiments of Bisbee *et al.* that might cause the enthalpy of formation to be too negative. We adopt the value of 24.52 $kJ \cdot mol^{-1}$, reported by King and Armstrong.[1]

Heat Capacity and Entropy

The structural parameters are those reported by Pierce *et al.*[5] for the average ground state molecule from the microwave spectrum. Earlier measurements of Hilton *et al.*[6] disagree but according to Pierce *et al.*,[7] the line assignments used by Hilton *et al.* are incorrect. The microwave study of Morino and Saito[8] yielded r_e = 1.4053 Å and an angle of 103°4' which is in agreement with our adopted values. The principle moments of inertia (in $g \cdot cm^2$) are: $I_A = 1.4392 \times 10^{-39}$, $I_B = 7.7225 \times 10^{-39}$, and $I_C = 9.1617 \times 10^{-39}$.

We adopt the vibrational frequencies reported by Jones *et al.*,[9] several other investigators reported similar values.[10–12] Nebgen *et al.*[13] obtained the harmonic frequencies and the anharmonic constants for the three vibrations.

There are numerous more recent studies focusing on Fermi resonance and Coriolis coupling but the results support our adopted values.

Product of the Moments of Inertia: $I_A I_B I_C = 1.655344 \times 10^{-114}\ g^3·cm^6$

Enthalpy of Formation

The increment in $\Delta_f H°$ at 298.15 K between gaseous SOF_2 and SO_2F_2 is estimated from increments for the four pairs a) S and SO, b) SO and SO_2, c) SO_2 and SO_3, and d) $SOCl_2$ and SO_2Cl_2. Based on $\Delta_f H° = -181.3\ kcal·mol^{-1}$ for SO_2F_2[1], we derive a) −116, b) −109, c) −158, and d) −148 for $\Delta_f H°$ of SOF_2(g). The derivation is based on $\Delta_f H°(SOCl_2, g, 298.15\ K)$.[1,2] Giving lesser weight to c) which involves SO_3, we adopt an average of $-130 \pm 25\ kcal·mol^{-1}$.

Heat Capacity and Entropy

The molecular structure is from the microwave study of Ferguson.[3] Principal moments of inertia are $I_A = 9.7369 \times 10^{-39}$, $I_B = 10.0399 \times 10^{-39}$, and $I_C = 16.9332 \times 10^{-39}\ g·cm^2$. Vibrational frequencies are those assigned by Pace and Samuelson[4] from their gas phase infrared spectra. These authors also measured Raman spectra of liquid and gas and summarized earlier spectral studies. We adopt ν_1 as the lower wave number of the Fermi resonance doublet at 1330 and 1340 cm^{-1}. Uncertainty is greatest for the overlapping bands near 378 and 392 cm^{-1}.

Pace and Turnbull[5] derived $S° = 63.56 \pm 0.15\ cal\ K^{-1}·mol^{-1}$ for the ideal gas at $T_{vap} = 228.84$ K from calorimetric measurements of heat capacity (12 to 230 K), $\Delta_{fus}H°$, and $\Delta_{vap}H°$. Spectroscopic data of this table yield the corresponding value of $S° = 63.29$ which is 0.27 cal $K^{-1}·mol^{-1}$ smaller than observed. Pace and Turnbull attributed the minor discrepancy to bias in the measurements of $\Delta_{vap}H°$.

Ground State Quantum Weight: [1] $\sigma = 2$
Point Group: [C_{2v}]
Bond Distances: Si–O = [1.60] Å; Si–F = [1.54] Å
Bond Angles: F–Si–O = [120]°; F–Si–F = [120]°
Product of the Moments of Inertia: $I_A I_B I_C$ = [2.565383 × 10^{-114}] $g^3·cm^6$

Enthalpy of Formation

$\Delta_f H°(SiOF_2, g, 298.15\ K)$ is estimated by comparison with those for SiF_4(g) and SiO_2(g).

Heat Capacity and Entropy

The vibrational frequencies were estimated by comparison with those for COF_2(g) and TiOF(g). The vibrational frequencies for COF_2(g) and $TiOF_2$(g) were obtained from Lovell *et al.*[1] and Gordon,[2] respectively. The bond distances of Si–O and Si–F were assumed to be the same as those for SiO(g) and SiF_4(g), respectively. Point group, ground state multiplicity, and bond angles were estimated.

Ground State Quantum Weight: [1] $\sigma = 2$

Point Group: [C_{2v}]

Bond Distances: Ti–O = [1.62] Å; Ti–F = [1.74] Å

Bond Angle: O–Ti–F = [120]°

Product of the Moments of Inertia: $I_A I_B I_C = [4.344131 \times 10^{-114}]\ g^3·cm^6$

Enthalpy of Formation

$\Delta_f H°(0\ K)$ was estimated as $-220\ kcal·mol^{-1}$ by Gordon.[1] $\Delta_f H°(298.15\ K)$ was then calculated.

Heat Capacity and Entropy

Molecular constants were estimated by Gordon.[1] The principal moments of inertia are: $I_A = 11.6652 \times 10^{-39}$, $I_B = 14.3272 \times 10^{-39}$, and $I_C = 25.9925 \times 10^{-39}\ g·cm^2$.

Point Group: C_s $\sigma = 1$

Bond Distances: F–O = 1.575 Å; O–O = 1.217 Å

Bond Angles: O–O–F = 109°30'; dihedral angle = 87°30'

Product of the Moments of Inertia: $I_A I_B I_C = 1.3348 \times 10^{-114}\ g^3 \cdot cm^6$

Enthalpy of Formation

A critical measurement for the calculation of the thermodynamic functions for both O_2F and O_2F_2 is the standard enthalpy of formation of O_2F_2 by Kirshenbaum *et al.*[1] These authors made a calorimetric measurement at 190 K for decomposition of O_2F_2 into O_2 and F_2. Conversion of that measurement from 190 K to the standard enthalpy of formation at 298 K required knowledge of the difference in constant–volume heat capacity between the reactant (O_2F_2) and the products (O_2 and F_2). The authors assumed that difference to be zero over the entire range. With the published heat capacities for fluorine and oxygen, plus that for O_2F_2 reported here, we find that the average heat capacity difference over the 190 to 298 K temperature range to be 1.41 cal $K^{-1} \cdot mol^{-1}$. The standard enthalpy of formation that Kirshenbaum *et al.*[1] reported was $\Delta_f H°(O_2F_2, 298.15\ K) = 19.8 \pm 1.3\ kJ \cdot mol^{-1}$. With the heat capacity correction suggested by Lyman,[2] it became $\Delta_f H°(O_2F_2, 298.15\ K) = 19.2 \pm 0.84\ kJ \cdot mol^{-1}$ as suggested by Lyman.[2]

The value adopted is that recommended by the evaluation of Lyman,[2] with an increased uncertainty.

Heat Capacity and Entropy

The structure of this molecule is estimated to be a nonlinear chain with an O–O–F bond angle of 109°30' and a dihedral angle 87°30'. The adopted bond lengths are r(F–O) = 1.575 Å and r(O–O) = 1.217 Å from the microwave study of Jackson.[3] The principle moments of inertia (in $g \cdot cm^2$) are: $I_A = 4.1409 \times 10^{-39}$, $I_B = 1.6747 \times 10^{-38}$, $I_C = 1.9247 \times 10^{-38}$.

The vibrational frequencies are those recommended in the review by Jacox.[4] For $\nu_1 - \nu_5$ we adopt the gas phase results (rather than the matrix isolation matrix) of Kim and Campbell.[5] For ν_6 we adopt the results of Spratley *et al.*[6] which were derived from oxygen matrix isolation studies. For ν_2, ν_3 and ν_5, these matrix isolation studies agree within 6 cm^{-1} of the gas phase results. The matrix isolation results of Arkell,[7] Gardiner *et al.*[8] and Jacox[4] are in support of these values.

Product of the Moments of Inertia: $I_A I_B I_C = 4.490464 \times 10^{-114}\ g^3 \cdot cm^6$

Enthalpy of Formation

Ruh *et al.*[1] reported percent conversions for the reaction $SO_2(g) + Cl_2(g) + 2\ HF(g) \rightarrow SO_2F_2(g) + 2\ HCl(g)$ at 110 to 700°C and at pressures slightly above atmospheric. The data allow calculation of apparent values of K_p from the assumption of exact stoichiometry. Two temperatures may be excluded, namely 110°C for failure to approach equilibrium and 597°C due to power failure. The remaining values (503 to 973 K) yield $\Delta_r H°$(3rd law) = −24.15 ± 2 and $\Delta_r H°$(2nd law) = −20.7 ± 1.6 $kcal \cdot mol^{-1}$ at 298.15 K. The 3rd law values show a minor trend with temperature, corresponding to $\Delta_r S°$(2nd law) $-\Delta_r S°$(3rd law) = 5.4 ± 2.5 cal $K^{-1} \cdot mol^{-1}$, but this inconsistency is small enough to suggest that there was reasonable approach to equilibrium. An example given in the text of the patent[1] reveals that the actual recovery of SO_2 was somewhat less than that predicted on the assumption of stoichiometry. Use of this actual recovery of SO_2 would make $\Delta_f H°$(3rd law) more negative by less than 0.4 $kcal \cdot mol^{-1}$. We adopt $\Delta_f H° = -24.15\ kcal \cdot mol^{-1}$ and $\Delta_f H° = -181.3 \pm 2\ kcal \cdot mol^{-1}$ at 298.15 K.

Reese *et al.*[2] derived $\Delta_f H° = -205\ kcal \cdot mol^{-1}$ from electron impact studies. They measured potentials of 12.44 ± 0.1 and 19.9 ± 0.3 eV for the appearance of SO_2^+ from SO_2 and SO_2F_2, respectively. Combination of these values implies that $\Delta_f H°$ of SO_2F_2 should be about 1.0 eV more negative than the adopted value. This discrepancy could reasonably arise from neglect of the unknown excess energies of the products of the two reactions. Bond–energy comparisons tend to confirm this view. Average values of $D_0°$(S–F) may be calculated from $\Delta_f H°/2$ for $SF_6 \rightarrow SF_4 + 2\ F$ and $SO_2F_2 \rightarrow SO_2 + 2F$. $D_0°$(S–F) = 72 $kcal \cdot mol^{-1}$ from SF_6 is much more consistent with $D_0°$(S–F) = 74 $kcal \cdot mol^{-1}$ from the adopted $\Delta_f H°$ than with $D_0°$(S–F) = 86 $kcal \cdot mol^{-1}$ from the electron impact value.

Heat Capacity and Entropy

Bond lengths and bond angles are from the microwave study of Lide *et al.*[3] The resulting O–S–F angle is 108.3° and the principal moments of inertia are $I_A = 16.3467 \times 10^{-39}$, $I_B = 16.5727 \times 10^{-39}$, and $I_C = 16.5756 \times 10^{-39}\ g \cdot cm^2$. An early electron–diffraction study[4] is in reasonable agreement.

Vibrational frequencies are those assigned by Lide *et al.*[5] based on additional microwave and infrared data for the gaseous and matrix–isolated phases. Assignment of the three fundamentals near 544 cm^{-1} and the two near 388 cm^{-1} is supported by gas phase Raman spectra,[6] by combination and overtones in the infrared[6] and by force–field calculations.[7]

Calculated values of $C_p°$ agree within 0.1% with those derived by Gehri[8] from measurements of $C_p°$ at temperatures of 273 to 323 K and pressures up to 1 atm. The calculated entropy, $S° = 63.25$ cal $K^{-1} \cdot mol^{-1}$ at the normal boiling point of 217.78 K, may be compared with 62.66 ± 0.15 cal $K^{-1} \cdot mol^{-1}$ derived from low–temperature calorimetric data by Bockhoff *et al.*[9] The discrepancy is 0.59 cal $K^{-1} \cdot mol^{-1}$; it was attributed[9] to randomness in the solid at absolute zero. Bockhoff and Pace[10] later reported an entropy discrepancy of 1.48 cal $K^{-1} \cdot mol^{-1}$, but this value resulted from an incorrect vibrational assignment.[5–7]

Enthalpy of Formation

The adopted results are $\Delta_fH°(0\ K)$ = 112.2 ± 5.0 kcal·mol^{-1}, $D_0°$ (PF-F) = 122.0±10.0 kcal·mol^{-1}, and $\Delta_{at}H°$ = 228.1 ± 6.0 kcal·mol^{-1}. We estimate $\Delta_fH°$ such that the value gives $D_0°$ (PF–F)/$\Delta_{at}H°(0\ K)$ = 0.535. The value of this ratio is selected from those for SiF_2(0.54 ± 0.03) and SF_2(0.53 ± 0.05) which are calculated from the most recent JANAF tables.[1] Two previous estimates of $\Delta_fH°$ are available for comparison. O'Hare[2] used the relationship $D_0°$ (PF_2–F) = 1.1 $\Delta_{at}H°(PF_3)$ to obtain a $\Delta_fH°$ of −115.7 ± 5 kcal·mol^{-1}. This estimate agrees quite well with the results adopted here. An earlier JANAF table[3] gives $\Delta_fH°(PF_2)$ = −104.7 ± 15.0 kcal·mol^{-1} which was based on an estimate value for the $\Delta_{at}H°$ of PF_3. We estimate that the uncertainty in the value of the ratio $D_0°/\Delta_{at}H°$ should not exceed ±0.06 which corresponds to an uncertainty in $\Delta_fH°$ of ±5.0 kcal·mol^{-1}.

Heat Capacity and Entropy

The results of electron spin resonance experiments[4,5] and molecular orbital calculations[4,6,7] are consistent with PF_2 having C_{2v} symmetry; however, no experimental determination of the structural parameters has been reported. Numerous values for the bond length and angle have been proposed based on energy optimization[6,7] and other estimation techniques.[2,4,8,9] These estimates are widely scattered with the bond lengths ranging from (1.52 to 1.73 Å) and the bond angles ranging from 98.6 to 112°. We prefer to use molecular parameters similar to those measured[10] for the related molecule PF_2H. The adopted values appear quite reasonable by comparison with structural data[1] for SiF_2 and SF_2. The principal moments of inertia are: I_A = 2.9836 × 10^{-39}, I_B= 9.1077 × 10^{-39}, and I_C = 12.0913 × 10^{-39} g·cm^2.

The two stretching frequencies (ν_1 and ν_3) have been observed[11] in the infrared spectrum of PF_2 formed in an argon matrix by photolysis of PF_2H. The adopted values are rounded to the nearest cm^{-1}. The bending frequency (ν_2) is calculated from the force constant f_α/r^2 = 0.495 mdyn/Å. We obtain the bending force constant from the ratio $f_r/(f_\alpha/r^2)$ equal to 9.59 which is the value calculated for SiF_2.[1]

The ground state is expected to be $^2B_1$, as shown by Wei *et al.*[4] We assume that the upper electronic levels and their corresponding quantum weights are the same as those previously estimated for the isoelectronic SF_2^+ ion. The procedure used to estimate these levels is thoroughly discussed on the SF_2^+ table.[1]

This table essentially updates the functions previously tabulated by O'Hare.[2]

Enthalpy of Formation

A summary of the information available on the appearance potential of PF_2^+ from PF_3 is presented below. We analyze these electron–impact results using the expression $\Delta_f H°(0\ K) = AP - E^*$ by assuming that the dissociative ionization process is $PF_3(g) + e^- = PF_2^+(g) + F(g) + 2\ e^-$. Values of $\Delta_f H°$ and the ionization potential are derived by setting E* in the above expression equal to zero. As a result, the values are listed in the table as inequalities to emphasize that they are limiting (upper) values.

Source	AP(PF_2^+/PF) eV	$\Delta_f H°(PF_2^+, g, 0\ K)$ kcal·mol^{-1}	IP(PF_2) eV
[1]	15.4 ± 0.2	<112.78	<9.76
[2]	15.7 ± 0.5	<119.70	<10.06
[3]	15.5 ± 0.2	<115.09	<9.86
[4]	13.5	<68.97	<7.86

The results derived from the first three studies[1–3] are in excellent accord, and we adopt the mean values of $\Delta_f H° = 115.861 \pm 8.0$ kcal·mol^{-1} and IP = 9.89 eV. Dean *et al.*[4] were unable to offer an explanation as to why their results were significantly lower than the other literature data. This study[4] indicates that $IP(PF_2) < IP(PCl_2)$ [3] which we believe is very unlikely. Harland *et al.* [1] have reported the AP for PF_2^+ from PF_2CN as 13.4 ± 0.2 eV, suggesting the possibility that the precursor responsible for the PF_2^+ ion in the measurements of Dean *et al.*[4] was PF_2CN rather than PF_3. A MO study[5] gave $IP(PF_2) = 9.88$ eV based on IP(P) – 10.98 eV. Recalculation of their results using a more recent value of IP(P) = 10.486 eV[6] gives $IP(PF_2) = 9.88$ eV. Our adopted value of IP (9.89 eV) is close to that for atomic phosphorus (10.49 eV). This is consistent with the results of electron spin resonance experiments[7,8] and MO calculations [5,7,9,10] which show that the ionizing orbital is slightly antibonding and located primarily on the phosphorus atom.

The mean bond energy (products $P^+(g)+2F(g)$) is 120.9 kcal·mol^{-1} which when compared with that for PF_2(114.1 kcal·mol^{-1}),[11] suggests that the bonding is somewhat stronger in the positive ion. This predicted increase in bond strength upon ionization is also consistent with the antibonding nature of the ionizing orbital. $\Delta_f H°$ (298.15 K) is calculated to be 117.049 kcal·mol^{-1}.

Heat Capacity and Entropy

The molecular parameters and vibrational frequencies are assumed to lie between those for PF_2 and SiF_2.[11] The electronic levels and quantum weights are estimated by analogy with those for the isoelectronic molecule SiF_2.[11] The principal moments of inertia are: $I_A = 2.8983 \times 10^{-39}$, $I_B = 9.4974 \times 10^{-39}$, and $I_C = 12.3957 \times 10^{-39}$ g·cm^2.

Enthalpy of Formation

The PF_2^- anion has been observed in the negative ion mass spectra of PF_3[1] and PF_2CN.[2] Both studies included thermochemical calculations on plausible ion formation processes, showing that the measured appearance potentials contained large excess energy contributions. At present, definite values cannot be assigned to these contributions; thus, their studies are of little value in defining $\Delta_f H°$.

Two estimates of the electron affinity of PF_2 have been reported.[2,3] Harland *et al.*[2] considered differences in bond energies for diatomic and triatomic species to obtain a value of EA(PF_2) = 1.4 eV. Rescaled CNDO calculations[3] have led to an EA = 1.71 eV. JANAF data[4] on the S–F system indicate that the EA values alternate between the even − and odd − electron molecules, with the odd–electron molecules having the higher EA values. Assuming the same trend is followed in the P–F system, we predict that EA(PF_2) > EA(PF) which is equal to 1.1 ± 0.5 eV.[4] We adopt an EA of 1.5 ± 0.5 eV for the reaction $PF_2^-(g) = PF_2(g) + e^-$ at 0 K which leads to $\Delta_f H°(PF_2^-, g, 0\ K) = -146.822 \pm 16.5\ kcal \cdot mol^{-1}$ with $\Delta_f H°(PF_2, g, 0\ K) = -112.23 \pm 5.0\ kcal \cdot mol^{-1}$.[4] The adopted value of EA is close to that for atomic phosphorus (0.77 ± 0.05 eV).[5] This is in agreement with results of MO calculations[3,6] and electron spin resonance experiments[6,7] which show that the electron captured by PF_2 goes into an antibonding orbital which is located primarily on the phosphorus atom.

$\Delta_f H°$ at 298.15 K and the fluoride–ion affinity (IA) are calculated to be $-148.594\ kcal \cdot mol^{-1}$ and $78.2\ kcal \cdot mol^{-1}$, respectively. The mean bond energy $\Delta_{at}H°/2$(products P(g) + F(g) + F^-(g)) is 92.2 $kcal \cdot mol^{-1}$ which is 21.9 $kcal \cdot mol^{-1}$ less than that for PF_2(114.1 $kcal \cdot mol^{-1}$).[4] The predicted decrease in the bond strength for the anion is also consistent with the antibonding nature of the electron orbital.

Heat Capacity and Entropy

The molecular parameters and vibrational frequencies are assumed to lie between those for PF_2 and SF_2.[4] The ground state is assumed to be a singlet since PF_2^- has no unpaired electrons. Also, we neglect excited states since these probably lie at energies which would not contribute to the partition function (refer to the table for the isoelectronic species SF_2). The principal moments of inertia are: $I_A = 3.0833 \times 10^{-39}$, $I_B = 9.0858 \times 10^{-39}$, and $I_C = 12.1691 \times 10^{-39}\ g \cdot cm^2$.

[6]	$3/2\ PbF_2(cr) + Al(cr) = 3/2\ Pb(cr) + AlF_3(cr)$	calor.	-117.7 ± 0.6	-162.2 ± 1.0

The samples used by Gross *et al.*[4, 5] could easily be β-PbF_2 rather than α-PbF_2. Other reactions[7, 8, 9] have led to values near $\Delta_f H°(298.15\ K) = -161.8\ kcal \cdot mol^{-1}$ [10] this value is adopted and is assigned an uncertainty of $\pm 2\ kcal \cdot mol^{-1}$.

The adopted enthalpy of formation is supported by measurements[11] of the reaction $PbF_2(cr) + Be(cr) = BeF_2(cr) + Pb(cr)$ from which the enthalpy of formation of BeF_2(cr) agrees with that from the direct fluorination of beryllium metal if the adopted value for $\Delta_f H°(PbF_2, \alpha, 298.15\ K)$ is used.

Heat Capacity and Entropy

The enthalpy of α-PbF_2(cr) was measured by Linsey.[12] Twenty data points (320–728 K) were obtained using a sample encapsulated in gold while fifteen were obtained (370–595 K) using a sample encapsulated in Nichrome V. We adopt the heat capacity values calculated by Linsey[12] and extrapolate linearly to 1000 K. It should be noted, however, that Linsey[12] adjusted his experimental enthalpy for α-PbF_2(cr) so that when the orthorhombic sample was heated above T_{trs}, the resulting enthalpy was consistent with the cubic PbF_2 enthalpy.

There is no low temperature heat capacity data for α-PbF_2(cr). We estimate $S°(298.15\ K) = 27.0 \pm 2.0\ cal\ K^{-1} \cdot mol^{-1}$.

Transition Data

The transition temperature is that obtained by Linsey[12] via enthalpy measurements on orthorhombic PbF_2. When heated above T_{trs}, orthorhombic PbF_2 changes quickly to the cubic form. Upon cooling the transformation is very sluggish.

The enthalpy of transition at room temperature, $240 \pm 9\ kcal \cdot mol^{-1}$, was determined by Linsey[12] by the differences in the heat of solution of the orthorhombic and cubic modifications in 1.0 M $Fe(NO_3)_3$. $\Delta_{trs}H°$ is calculated from this value using the enthalpy differences $H°(583\ K) - H°(298.15\ K)$ for the cubic and orthorhombic modifications.

$S°(298.15\ K) = [114.398]\ J·K^{-1}·mol^{-1}$
$T_{trs} = 583 \pm 1\ K$
$T_{fus} = 1103 \pm 2\ K$

$\Delta_f H°(298.15\ K) = [-675.990]\ kJ·mol^{-1}$
$\Delta_{trs} H° = 1.463\ kJ·mol^{-1}$
$\Delta_{fus} H° = 14.728 \pm 1.3\ kJ·mol^{-1}$

Enthalpy of Formation

Linsey[1] determined the heat of transition at room temperature to be 240 ± 9 $kcal·mol^{-1}$ from heat of solution measurements of the orthorhombic and cubic modifications in 1 M $Fe(NO_3)_3$. We calculate and adopt $\Delta_f H°(PbF_2, \beta, 298.15\ K)$ by adding this heat of transition value to the $\Delta_f H°(298.15\ K)$ value for PbF_2(cr, α).

Other enthalpy of formation values derived from the enthalpy changes of different chemical reactions are tabulated below. Due to a lack of sample characterization we can only assume from the sample preparation and experimental conditions that the following reactions involve β–PbF_2(cr).

Source	Reaction	Method	$\Delta_f H°(298.15\ K)$ $kcal·mol^{-1}$	$\Delta_f H°(298.15K)$ $kcal·mol^{-1}$
[2]	$PbF_2(\beta) + H_2(g) = Pb(l) + 2\ HF(g)$	Press	32.0	−161.3
[3]	$PbF_2(\beta) + H_2O(g) = PbO(cr) + 2\ HF(g)$	Press	30.06	−154.6
[4]	$1/2\ PbF_2(\beta) + 1/3\ Al(cr) = 1/2\ Pb(l) + 1/3\ AlF_3(cr)$	emf	−116.39	−162.0

The two studies by Gross *et al.*[5,6] may well involve β-PbF_2. Kolesov *et al.*[7] used two PbF_2 samples which had been fused. These samples should then be in the β-modification. The results are considerably different from those given in the α–PbF_2 table[8] for α–PbF_2.

Heat Capacity and Entropy

Linsey[1] measured the enthalpy of cubic PbF_2. The enthalpy data (61 data points, 321–1164 K) revealed an anomaly in the enthalpy and heat capacity in the range 573–823 K. Linsey[1] interpreted the results in terms of a lambda-type (cooperative) transition in the heat capacity with a maximum at 716 K. We adopt the heat capacity values calculated and reported by Linsey.[1]

Banashek *et al.*[8] measured the high temperature enthalpies in the range 670–1165 K. Their data is consistent with the interpretation of Linsey.[1]

The entropy is calculated in a manner analogous to that used for the enthalpy of formation.

Fusion Data

Refer to the liquid table for details.

PREVIOUS: CURRENT: December 1973

$S°(298.15\ K) = [130.927]\ J·K^{-1}·mol^{-1}$ $\Delta_f H°(298.15\ K) = [-660.320]\ kJ·mol^{-1}$

$T_{fus} = 1103 \pm 4\ K$ $\Delta_{fus}H° = 14.728 \pm 2.1\ kJ·mol^{-1}$

Enthalpy of Formation

$\Delta_f H°(PbF_2, l, 298.15\ K)$ is calculated from $\Delta_f H°(PbF_2, cr, \beta, 298.15\ K)$ by adding the enthalpy of fusion, $\Delta_{fus}H°$, and the difference in enthalpy, $H°(1103\ K)-H°(298.25\ K)$, between the β–crystal and liquid.

Heat Capacity and Entropy

The enthalpies of PbF_2(l) in the temperature range 1104–1165 K were determined by Banashek *et al.*[1] Based on their reported results, the heat capacity of PbF_2(l) is evaluated to be 24 ± 2 cal $K^{-1}·mol^{-1}$ by the least square method. Linsey[13] measured the enthalpy of PbF_2(l) in the range 1105–1164 K (8 data points) and reported a constant heat capacity value of 26.10 cal $K^{-1}·mol^{-1}$. We adopt this value and extrapolate to 700 K and 1500 K. A glass transition is assumed at 700 K below which the heat capacity values of cubic PbF_2 are used.

$S°(298.15\ K)$ is calculated in a manner analogous to that used for the enthalpy of formation.

Fusion Data

T_{fus} and $\Delta_{fus}H°$ are taken from the enthalpy data of Linsey.[13] Our analysis of the enthalpy data of Banashek *et al.*[1] yields a heat of melting value of 2.98 kcal·mol^{-1}.

Other values of T_{fus}(K) reported are 1091,[2, 11] 1097,[3, 4, 5] and 1128.[6] Using the freezing point data of binary systems PbF_2–$PbBr_2$,[5] PbF_2–$PbCl_2$,[5, 7] PbF_2–PbI_2,[5, 8] PbF_2–PbO,[9] and PbF_2–NaF.[10] Kelley[3] evaluated the corresponding values of $\Delta_{fus}H°$ kcal·mol^{-1} as 1.70, 1.70, 1.96, 3.87, and 2.47. Other reported values of $\Delta_{fus}H°$ are 3.00[1] and 4.16[2] kcal·mol^{-1}.

Vaporization Data

From mass spectroscopic study on the vapor species in PbF_2, Zmbov *et al.*[4] have shown that molten PbF_2 vaporizes partly as molecular PbF_2. There is considerable disproportionation, and at 988 K the vapor composition is approximately 66% PbF_4, 25% PbF_2, 2% PbF, and 7% Pb.[4, 12] T_{vap} has been reported as 1565 K[11] where the vapor is expected to be a mixture of the above species.

Enthalpy of Formation

Vapor pressure data for PbF_2 have previously been interpreted on the assumption that PbF_2 was the only species present in the gas phase.[1,2] Zmbov *et al.*[3] have studied the vapor species over PbF_2(cr, l) mass spectrometrically and shown that PbF_2vaporizes only partly as molecular PbF_2 and there is considerable disproportionation. The vapor composition at 988 K is approximately 66% PbF_4, 25% PbF_2, 2% PbF, and 7% Pb.[3,4] From extrapolation of the ion intensity data from 1043 to 988 K to the temperature region in which Nesmeyanov and Iofa[2] measured the saturated vapor pressures of PbF_2(cr), 792–988 K, by Knudsen effusion method, the partial pressure of PbF_2(g), at 988 K was calculated to be 0.0435 ± 0.005 torr. Based on this calculated vapor pressure, the enthalpy of sublimation $\Delta_{sub}H°(298.15\ K)$ of PbF_2(cr, β) is derived as 57.53 $kcal·mol^{-1}$ by the 3rd law method, yielding $\Delta_f H°(PbF_2, g, 298.15\ K) = -104.0 \pm 2\ kcal·mol^{-1}$.

Due to lack of data on vapor compositions over PbF_2 at various temperatures, the total pressure measurements reported by Wartenberg and Bosse,[1] using boiling point method, and those of Nesmeyanov and Iofa[2] are not used for evaluation.

The adopted $\Delta_f H°(298.15\ K)$ leads to an atomization energy $\Delta_{at}H°(0\ K) = 8.10$ eV for the process $PbF_2(g) = Pb(g) + 2F(g)$, using auxiliary data.[5]

Heat Capacity and Entropy

The bond distance was determined by Akishin *et al.*[6] The bond angle was estimated by Hauge *et al.*[7] from a Group IV A difluoride comparison. Hauge *et al.*[7] determined the vibrational frequencies from the infrared spectra of neon matrix isolated PbF_2(g).

Enthalpy of Formation

We calculate $\Delta_f H°$ from a 3rd law analysis of two sets of equilibrium data for the gaseous isomolecular reaction $S + SF_2 = 2\ SF$. The equilibrium data are obtained from ion currents reported in a mass spectrometric study[1] of the molecular species formed from the reaction of gaseous SF_6 with graphite. We do not include in the equilibrium constants a proportionality constant involving ion multiplier gain and ionization cross sections since Hildenbrand[1] has recently demonstrated that these factors tend to cancel for isomolecular reactions. Results of our analyses are presented below.

Series	Cell Configuration	Data Points	T/K	$\Delta_f H°$(298.15 K), kcal·mol^{-1} 2nd law	3rd law	Drift cal·K^{-1}·mol^{-1}	$\Delta_f H°$(298.15 K) kcal·mol^{-1}
[2]	C cell/wound Pt wire	4	1436–1564	3.1	10.68 ± 0.7	5.0 ± 2.3	70.77 ± 4.0
[3]	C cell/Pt partition/packed with cloth and Pt wire	7	1478–1588	7.7	10.87 ± 0.9	2.1 ± 5.0	70.96 ± 4.0

The two cell configurations used by Hildenbrand[1] yield nearly identical 3rd law $\Delta_f H°$ values; thus, we adopt the rounded average of −70.9 ± 4.0 kcal·mol^{-1}. Our adopted $\Delta_f H°$ value corresponds to a enthalpy of atomization and average bond dissociation energy of 172.9 kcal·mol^{-1} and 86.4 kcal·mol^{-1}, respectively. In addition, the primary bond dissociation energy of SF_2 is calculated to be $D_0°$(SF–F) = 91.7 kcal·mol^{-1}, suggesting that the individual S–F bonds are somewhat stronger than that in the SF (81.2 kcal·mol^{-1})[2] radical. This increase in bond strength is predicted by MO calculations[3] and has been qualitatively accounted for in terms of the valence-state model[1] of covalent bonding.

Two additional pieces of information exist which provide some support for our selected $\Delta_f H°$ value. Kinetic studies[4] on the dissociation of SF_3 indicate that $D_0°(SF_2–F)$–72 kcal·mol^{-1}. We calculate $D_0°(SF_2–F)$ = 67.3 kcal·mol^{-1} from JANAF data,[2] indicating that our heats of formation for SF_3 and SF_2 are consistent with these kinetic results. Di Lonardo and Trombetti[5] obtained $D_0°$(SF–F) = 92.2 ± 12 kcal·mol^{-1} from electron–impact threshold measurements on the COS/F and SF_6 systems. This value is to be compared with our calculated value of 91.7 kcal·mol^{-1}.

Heat Capacity and Entropy

We adopt molecular data which refer to an average ground state structure for SF_2. These results are based on microwave measurements and force field calculations performed by Kirchhoff *et al.*[6] Earlier microwave spectroscopic observations[7] on the isotopic $^{34}SF_2$ species support the assignment of the spectrum to the difluoride and confirm its angular structure. The individual moments of inertia are: $I_A = 3.1377 \times 10^{-39}$, $I_B = 9.1367 \times 10^{-39}$, and $I_C = 12.2744 \times 10^{-39}\ g·cm^2$.

A recent review on the chemistry of the lower sulfur fluorides includes a discussion on the vibrational spectrum of SF_2.[8] The only observed vibrational frequency (830 cm^{-1}) which has so far been attributed to the difluoride appeared as a shoulder to a band at 810 cm^{-1} in the infrared spectra of a mixture of S–F compounds. The band at 810 cm^{-1} has been assigned[8] to the S–F equatorial stretching frequency of F_3SSF. We prefer not to adopt the 830 cm^{-1} frequency as a fundamental since the band cannot be positively identified as due to SF_2. Four sets[6,9–11] of estimated frequencies have been reported. We believe that the best estimates are those of Kirchhoff *et al.*[6] which we adopt. These frequencies were obtained from force field calculations and include corrections which were made to account for the differences found between predicted and observed fundamentals for the related molecules of OF_2, SO_2, SiF_2, and CF_2. By analogy with other even electron S–F species,[2] we predict that the ground state is singlet and that there are no low-lying electronic levels which would contribute to the partition function.

Our thermal functions essentially update those reported by Wilkins.[10] Another set of functions which cover a rather short (0–2000 K) temperature interval has been reported by O'Hare.[11] We believe, however, that his estimate (ν_2 = 523 cm^{-1})[11] of the bending frequency is too high based on that observed for SO_2(ν_2 = 517 cm^{-1})[2] indicating that his entropies are probably too low by as much as 0.6–0.8 cal K^{-1}·mol^{-1}.

Point Group: $[C_{2v}]$ $\sigma = [2]$

Bond Distance: S–F = [1.59] Å

Bond Angle: F–S–F = [100]°

Product of the Moments of Inertia: $I_A I_B I_C = [3.4931 \times 10^{-115}]\ g^3\cdot cm^6$

Enthalpy of Formation

$H°(0\ K) = 166.9 \pm 11.0\ kcal\cdot mol^{-1}$ is calculated as the sum of $\Delta_f H°(SF_3, g, 0\ K) = -70.42 \pm 4\ kcal\cdot mol^{-1}$ [1] and $IP(SF_2) = 10.29 \pm 0.3$ eV (237.29 $kcal\cdot mol^{-1}$). IP is the electron–impact appearance potential of SF_2^+ which was measured by Hildenbrand[2] in a mass spectral study of the products formed from the reaction of SF_6 with C at about 1500 K. We increase the uncertainty in IP to ±0.3 eV from the value (±0.1 eV) assigned by Hildenbrand[2] since recent photoelectron (PE) spectrometric studies on the related dihalides SCl_2[3] and SiF_2[4] show that their adiabatic ionization potentials lie 0.22 and 0.40 eV, respectively, below the corresponding vertical values. The adopted value of IP is bracketed by the accurately known adiabatic values for SCl_2(9.45 ± 0.05 eV),[3] and SiF_2(10.78 ± 0.05 eV),[4] and is close to the IP for atomic sulfur (10.36 eV).[5] MO calculations[6] predict $IP(SF_2) = 9.6$ eV.

Several fragmentation appearnce potentials for the ion–molecule systems SF_2^+/SF_6)[2,7] SF_2^+/SF_4,[2] and SF_2^+/NSF_3[8] have been reported and provide alternate paths leading to $\Delta_f H°$ once the ion formation processes are assigned. We use plausible reactions for the formation of SF_2^+ to calculate $\Delta_f H°$ values which cover the range 146–342 $kcal\cdot mol^{-1}$. The scatter in these values indicate that either the dissociative ionization processes have been incorrectly assigned, or perhaps more likely, the processes involve excess kinetic and/or excitation energies.

We find that the primary bond dissociation energy $D_0°$ (SF^+–F) is 87.1 $kcal\cdot mol^{-1}$ which when compared with $D_0°$ values [1] for SF_2(91.7 $kcal\cdot mol^{-1}$) and SF_2^-(68.7 $kcal\cdot mol^{-1}$) indicates that the trend is $D_0°(SF_2^+)$–$D_0°(SF_2) > D_0°(SF_2^-)$. Similar trends in bond dissociation energies have been reported[9] for the ions and neutrals of phosphorus and nitrogen difluorides.

Heat Capacity and Entropy

According to the Walsh correlation diagram[10] for non–hydride AB_2 molecules, the most loosely bound pair of electrons in SF_2 is in a b_1'' orbital. The Walsh prediction is supported by the results of theoretical studies[3, 11, 12] and assignments of the bands in the PE spectra[3, 12] for the isoelectronic molecules SCl_2, OF_2, and OCl_2. The b_1'' orbital is S–F antibonding and F–F bonding, but its binding energy[10] shows only a small positive angular dependence. We would expect then that removal of an electron from this orbital should be accompanied by a small increase in the bond angle. We adopt a bond angle of 100° which corresponds to roughly a 2° increase from that for SF_2.[1] The antibonding nature of the b_1'' orbital is also expected to produce upon ionization a decrease in the S–F bond length. However, a comparison of the S–F bond strengths in $SF_2^+(D_0° = 87.1\ kcal\cdot mol^{-1})$ and $SF_2(D_0° = 91.7\ kcal\cdot mol^{-1})$ would seem to indicate that any changes in molecular parameters are relatively small. We adopt $r_e(SF_2^+) = 1.59$ Å which amounts to only a 0.002 Å reduction from that for SF_2.[1] Our estimated molecular parameters appear reasonable in comparison with those for SiF_2.[1] The individual moments of inertia are: $I_A = 1.2375 \times 10^{-39}$, $I_B = 9.3597 \times 10^{-39}$, and $I_C = 3.0157 \times 10^{-39}\ g\cdot cm^2$.

We calculate the vibrational frequencies from the force constants $f_r = 4.7$ and $f_\omega/r^2 = 0.49$ mdyn/Å. The stretching force constant (f_r) is estimated from that for SiF_2[1] and PF_2.[13] We obtain the bending force constant from the ratio $f_r/(f_\omega/r^2) = 9.59$ which is the value calculated for SiF_2.[13] The changes in our frequencies on going from SF_2 to SF_2^+ are insignficant, in agreement with the view that the bonding in the two molecules is very similar.

The electronic configurations of the ground and excited states are predicted from the Walsh correlation diagram.[10] We also predict from this diagram that the two $^2A_1 \propto {}^2B_1$ spacings will strongly depend on the bond angle. This is supported at least for the first spacing by PE studies[3, 12] on SCl_2, OCl_2 and OF_2. Based on the similarity in the bond angles for OF_2[3] and SF_2,[1] we estimate the first $^2A_1 \leftarrow {}^2B_1$ spacing to be somewhat greater than that for OF_2^+(23471 cm^{-1}).[12] The PE spectra for SCl_2[3] and OF_2[12] do not provide support for the existence of a second $^2A_1$ state. This state has been observed, however, in the PE spectrum of OCl_2.[12] These results show for OCl_2^+ that the second $^2A_1$ state lies 2258 cm^{-1} above the first $^2A_1$ state. We include a second $^2A_1$–$^2A_1$ spacing of 3000 cm^{-1}. We estimate a somewhat larger spacing for SF_2^+ based on the fact that the bond angle in SF_2^+ is predicted to be smaller than that for OCl_2^+. The relative term value for the upper most state ($^2A_2$) is estimated from that for OF_2^+.[12]

Enthalpy of Formation

We calculate the adopted value of $\Delta_f H°(0\ K)$ = −93.5 ± 15.5 kcal·mol^{-1} as the difference between $\Delta_f H°(SF_2,g,0\ K)$ = −70.42 ± 4.0 kcal·mol^{-1} [1] and an estimate EA(SF_2) = 1.0 ± 0.5 eV (23.06 kcal·mol^{-1}). The value of EA is estimated from a consideration of trends in the electron affinities for other S–F species.[1] These data follow a regular pattern among the even–and odd–electron molecules, with the odd–electron molecules having, as expected, the higher electron affinities. Within each even– and odd– electron series, the EA values progressively increase as the number of fluorine atoms are increased in the ions. The only other estimate available to compare with our result is EA = 1.2 ± 0.5 eV. This estimate was made by Hildenbrand[2] who used a method similar to ours. Our $\Delta_f H°$ value corresponds to a fluoride–ion affinity for SF of IA = 36.4 ± 17.0 kcal·mol^{-1}, and $\Delta_f H°$ at 298.15 K is −95.2 kcal·mol^{-1}. In addition, we find that the primary bond dissociation energy $D_0°(SF^-–F)$ is 68.7 kcal·mol^{-1} which when compared with the values for SF_2(91.7 kcal·mol^{-1}) and SF_2^+(87.1 kcal·mol^{-1}) indicates that the trend is $D_0°(SF_2^+)$–$D_0°(SF_2) > D_0°(SF_2^-)$. Similar trends in bond dissociation energies have been reported[3] for the ions and neutrals of phosphorus and nitrogen difluorides.

JANAF data[1] predict that SF_2^- should be reasonably stable at moderate temperatures, with dissociative ionization ($SF + F^-$) becoming thermodynamically favorable above 1500 K. These predictions are qualitatively supported by the observations of Harland and Thynne[4,5] who have observed SF_2^- in the negative ion mass spectra of SF_6, SF_4, and SF_5Cl. The temperature of the ion source was reported as around 325 K.

Heat Capacity and Entropy

According to the Walsh correlation diagram[6] for non–hydride AB_2 molecules, the most loosely bound electron in SF_2^- is in an $\bar{a}_1'$ orbital whose binding energy falls markedly with an increase in bond angle. We predict then that electron capture by SF_2 should be accompanied by a large increase in bond angle. Based on the bond angle reported for the isoelectronic valence (21 electrons) molecule ClF_2(136 ± 15°),[7] we estimate an angle for SF_2^- of 130° which represents a 32° increase from that for SF_2.[1] The addition of an antibonding electron to SF_2 should also produce an increase in the S–F bond length. We estimate $r_e(SF_2^-) = r_e(Cl–F)$ = 1.63 Å[1] which corresponds to $r_e(SF_2^-)–r_e(SF_2)$ = 0.038 Å. The individual moments of inertia are: I_A = 1.3702 × 10^{-39}, I_B = 13.7701 × 10^{-39}, and I_C = 15.1403 × 10^{-39} g·cm^2.

We calculate vibrational frequencies from the force constants f_r = 2.0 and f_α/r^2 = 0.27 mdyn/Å. These force constants are estimated from those for ClF_2(f_r = 1.94 and f_α/r^2 = 0.26 mdyn/Å) which are obtained from the bond angle and vibrational frequencies reported by Mamantov *et al.*[7] Our frequencies on going from SF_2 to SF_2^- show a large decrease, in agreement with the view that the additional antibonding electron weakens the bonding in the radical anion relative to the neutral molecule.

The Walsh correlation diagram[6] predicts a ground state electronic configuration of $^2A_1$ for a 21 valence electron molecule. In addition, the existence of two doublet excited states is highly probable. We omit these excited states since no spectroscopic information is available on these states for isoelectronic molecules which would allow us to estimate the relative term values. We speculate that these levels lie above 20000 cm^{-1}, and thus, their contributions to the thermal functions are probably small below 3000 K.

Enthalpy of Formation

No direct experimental measurement of $\Delta_f H°$ is available. We estimate a value from bond energy considerations. From a comparison of bond lengths and force constants for FSSF[1] and SF_4,[2] we expect that the S–F bond energies in FSSF would be quite similar to those for the axial S–F bonds in SF_4. We assume $D_0°(FSS–F) = D_0°(SF_3–F)_{axial}$ = 73.6 kcal·mol^{-1} which leads to the adopted value of $\Delta_f H°(S_2F_2, g, 0\ K) = -79.7$ kcal·mol^{-1}. We use auxiliary heat of formation data from JANAF[3] and estimate the uncertainty in $\Delta_f H°$ as ±10.0 kcal·mol^{-1}. A previous estimate (−83.5 kcal·mol^{-1}) has been reported by O'Hare[4] who derived this value by a procedure identical with that used here. $\Delta_f H°(298.15\ K)$ corresponds to −80.4 kcal·mol^{-1}, and the atomization energy is calculated from $\Delta_f H°$ to be 247.9 kcal·mol^{-1}.

FSSF is isomeric with SSF_2.[3] Qualitative evidence has been presented[1] which indicates that SSF_2 is the more stable isomer. From our estimated free energy data, we predict a Gibbs energy change for the isomerization reaction FSSF(g) = SSF_2(g) of −15.4 kcal·mol^{-1} at 298.15 K, indicating that SSF_2 is substantially more stable than FSSF. This conflicts with relative stability predictions based on results from two independent MO studies.[5,6] These semiempirical (CNDO/2) calculations indicate that the instability of FSSF relative to SSF_2 amounts to only about 2.0 kcal·mol^{-1}. If we assume that these MO calculations are correct, we calculate that $D_0°(FS–SF) > D_0°(S=SF_2)$ by roughly 7.0 kcal·mol^{-1}. This seems very unlikely in view of what is known[1] about the S–S linkages in the two isomers. Our adopted results give $D_0°(FS–SF)$ = 85.6 kcal·mol^{-1} which lies between that for SSF_2(90.4 kcal·mol^{-1}) and S_2O(79.9 kcal·mol^{-1}).[3]

Heat Capacity and Entropy

The structural data and vibrational frequencies are taken from the recent review of Seel[1] and are based on reliable experimental measurements. We note that the molecular characteristics of FSSF are unusual in that the S–S bond length (1.888 Å) is much shorter than that in HSSH(2.05 Å),[1] and nearly equal to those in S_2(1.889 Å), SSF_2(1.860 Å), and S_2O(1.884 Å).[3] In contrast, the S–F bonds are longer than those in most S–F species (~1.58 Å),[3] and nearly as long as the axial S–F bonds (1.646 Å),[3] in SF_4. Rationale[1] has been presented to explain these unique molecular features in terms of double bond ($F^-S{=}S^+–F$) formation. The individual moments of inertia are: $I_A = 7.3579 \times 10^{-39}$, $I_B = 30.4921 \times 10^{-39}$, and $I_C = 32.6808 \times 10^{-39}\ g \cdot cm^2$.

We assume that there is no free internal rotation in the molecule, and the contribution from the torsional oscillation (ν_4 = 182.5 cm^{-1}) is included in the vibrational partition function. Extended Huckel calculations[7] show that the potential barrier to internal rotation is high (~40 kcal·mol^{-1}), providing some justification for our treatment. We estimate that the uncertainty in our entropies above 2000 K should not exceed 1.0 cal K^{-1}·mol^{-1}. The UV spectra[1] of FSSF reveal no excited states which would be significant in our calculations. Since S_2F_2 has no unpaired electrons, we predict that the ground state is singlet.

Our thermal functions essentially extend those reported by Brown and Pez.[8] Other published functions[4,9] are based on estimated vibrational frequencies and are considered less reliable.

Heat of Formation

No direct experimental measurement of $\Delta_f H°$ is available. We estimate two values from bond energy considerations. Seel[1] has presented a detailed discussion on the bonding in S_2, S_2O, and SSF_2 and has shown from bond length and force constant correlations that the S = S linkages in these molecules are very similar. We assume that $D_0°(S=SF_2) = (D_0°(S_2) + D_0°(S_2O))/2 = 90 \pm 10$ kcal·mol^{-1} which gives $\Delta_f H°(SSF_2, g, 0\ K) = -94.7 \pm 14$ kcal·mol^{-1} when the value of $D_0°$ is combined with $\Delta_f H°(SF_2, g, 0\ K) = -70.4 \pm 4$ kcal·mol^{-1} and $\Delta_f H°(S, g, 0\ K) = 65.75 \pm .01$ kcal·mol^{-1}.[2] From a comparison of bond lengths and force constants[1,3] for the S–F bonds in SSF_2, and SF_4, we would expect that the mean S–F bond energies for these molecules are probably not too different. Values[2] for OSF_2 and SF_4 are 83.4 kcal·mol^{-1} and 80.0 kcal·mol^{-1}, respectively. Using $D_0°(S_2F–F) = 81.5 \pm 2.5$ kcal·mol^{-1}, we calculate $\Delta_r H°(0\ K) = 163.0$ kcal·mol^{-1} for the dissociation process $S_2F_2 = S_2 + 2F$ which leads to $\Delta_f H°(SSF_2, g, 0\ K) = -95.5 \pm 5.0$ kcal·mol^{-1}. These two estimates are in reasonable agreement and we choose to adopt the value of -95.0 ± 10.0 kcal·mol^{-1}.

The heat of atomization $\Delta_{at}H°(0\ K)$ is calculated from our adopted $\Delta_f H°$ value to be 263.2 kcal·mol^{-1} which is close to the value of 262.0 kcal·mol^{-1} predicted by CNDO/2 MO calculations and energy partitioning methods.[4]

Published estimates[1,5,6] of $\Delta_f H°$ based on bond energy schemes similar to those used here include in kcal·mol^{-1} -92 ± 7, -80.2, and -86.4. Wilkins[6] assumed that the mean S–F bond energy for SSF_2 was 80.0 kcal·mol^{-1} and obtained $\Delta_f H° = -86.4$ kcal·mol^{-1}. We believe that this estimate is in error. Recalculation of his data gives $\Delta_f H° = -91.6$ kcal·mol^{-1} which is in much better agreement with our results.

Heat Capacity and Entropy

The structural data and vibrational frequencies are taken from the recent review by Seel[1] and are based on reliable experimental measurements. Since SSF_2 has no unpaired electrons, we predict that the ground state is singlet. The ultra violet spectra[1] show absorption peaks at roughly 34000 cm^{-1} and 42000 cm^{-1}, suggesting the existence of at least two excited states. We do not include the level near 42000 cm^{-1} since its effect is negligible. The individual moments of inertia are: $I_A = 10.2965 \times 10^{-39}$, $I_B = 21.0146 \times 10^{-39}$, and $I_C = 27.5332 \times 10^{-39}$ g·cm^2.

Our thermal functions essentially extend those reported by Brown and Pez.[7] Other published functions[5,6] are based on an older set of vibrational frequencies[8] and include a bias due to incorrect analysis of the SSF_2 structure. O'Hare's analysis[5] of the structural data resulted in a value for the product of the moments of inertia which is about 7% lower than our results. In addition, he assigned SSF_2 to point group C_{2V} and used a symmetry number of two rather than the correct value of one. The moments of inertia used by Wilkins[6] are in units of amu ucang,[2] not g cm^2 as assumed.

Point Group: C_{2v} $\sigma = 2$

Bond Distance: Si–F = 1.591 Å

Bond Angle: F–Si–F = 100° 59'

Product of the Moments of Inertia: $I_A I_B I_C = 3.200830 \times 10^{-115}\ g^3 \cdot cm^6$

Enthalpy of Formation

Margrave *et al.*[1] have reported some approximate equilibrium constants for the reaction Si(cr) + SiF_4(g) = 2 SiF_2(g). These were calculated from yields of polymerized products and a knowledge of the total system pressure given in U.S. Patent No. 2, 840,588 (1958). The data are subjected to a 3rd law analysis using the present JANAF functions[2] and yield $\Delta_f H°(298.15\ K) = 92 \pm 11\ kcal \cdot mol^{-1}$, which gives $\Delta_f H°(SiF_2, g, 298.15\ K) = -147 \pm 5\ kcal \cdot mol^{-1}$.

Ehlert and Margrave[3] and Farber[13] have determined equilibrium constants mass spectrometrically. A 2nd and 3rd law analysis of the data is shown below. We adopt $\Delta_f H°(SiF_2, g, 298.15\ K) = -140.5 \pm 3\ kcal \cdot mol^{-1}$ ($-587.852 \pm 12.6\ kJ \cdot mol^{-1}$).

Source	Reaction	T/K	Data Points	$\Delta_r H°(298.15\ K)$, $kcal \cdot mol^{-1}$ 2nd law	3rd law	Drift cal $K^{-1} \cdot mol^{-1}$	$\Delta_f H°(298.15\ K)$ $kcal \cdot mol^{-1}$
[3]	CaF_2(cr) + Si(g) = Ca(g) + SiF_2(g)	1395–1543	12	80.2 ± 14.1	88.0 ± 3.0	4.6 ± 9.7	−140.1
[3]	CaF_2(g) + Si(g) = Ca(g) + SiF_2(g)	1395–1543	12	−8.3 ± 14.1	−18.0 ± 3.0	−6.6 ± 9.6	−140.7
[3]	2 CaF(g) + Si(g) = 2Ca(g) + SiF_2(g)	1395–1543	12	−18.6 ± 7.5	−33.4 ± 1.8	−10.0 ± 5.1	−141.0
[13]	SiF_4(g) + Si(g) = 2SiF_2(g)	1590–1782	10	−2.0 ± 0.3	−3.2 ± 0.3	0.7 ± 0.8	−140.7

Using JANAF values,[2] we calculate $\Delta_{at} H°(0\ K) = 283.7 \pm 5\ kcal \cdot mol^{-1}$ for the process $SiF_2(g) = Si(g) + 2\ F(g)$. Within 2 $kcal \cdot mol^{-1}$ the average bond energies in SiF_2(g), SiF_3(g), and SiF_4(g) are the same.

Heat Capacity and Entropy

The electronic levels are adopted from the ultraviolet spectral work of Khanna *et al.*,[4] Rao[5] and Gole *et al.*[6] The vibrational assignments of $\nu_1 = 855\ cm^{-1}$ (symmetric stretch) and $\nu_3 = 872\ cm^{-1}$ (asymmetric stretch) of Khanna *et al.*[7] are adopted. These assignments are supported by the argon matrix studies of Milligan and Jacox,[8] the neon matrix and the argon matrix measurements of Hastie *et al.*[9] and the excited state microwave work of Shoji *et al.*[10] The bending frequency assignment, $\nu_2 = 345\ cm^{-1}$, is adopted from the ultraviolet and microwave study of Rao and Curl.[11] This assignment is also confirmed by Milligan and Jacox.[8]

The gas phase geometry was established by Rao *et al.*[12] from microwave spectra. The principal moments of inertia are: $I_A = 2.7474 \times 10^{-39}$, $I_B = 9.5072 \times 10^{-39}$, and $I_C = 12.2545 \times 10^{-39}\ g \cdot cm^2$.

$\Delta_f H°(298.15\ K) = -1217.126 \pm 2.9\ kJ \cdot mol^{-1}$
$\Delta_{trs} H° = [0.0]\ kJ \cdot mol^{-1}$
$\Delta_{trs} H° = [0.0]\ kJ \cdot mol^{-1}$
$\Delta_{fus} H° = 29.673 \pm 0.628\ kJ \cdot mol^{-1}$

Enthalpy of Formation

Guntz[1] measured the enthalpy of neutralization of $Sr(OH)_2$ (aq) with HF(aq) as $\Delta H = -35.8$ kcal·mol^{-1} at 284 K. We estimate a $\Delta C_p° = 105$ cal K^{-1}·mol^{-1} for $Sr(OH)_2 \cdot 555\ H_2O + 2(HF \cdot 110\ H_2O) \rightarrow SrF_2$(cr) + 2 H_2O(l) which gives $\Delta H(298.15\ K) = -34.1$ kcal·mol^{-1}. This value leads to $\Delta_f H°(SrF_2, cr, 298.15\ K) = -291.3$ kcal·mol^{-1} when combined with the following enthalpies of formation: $\Delta_f H°(H_2O, l, 298.15\ K) = -68.315$[2] $\Delta_f H°(Sr(OH)_2 \cdot 555\ H_2O, 298.15\ K) = -240.1$[3] and $\Delta_f H°(HF \cdot 110\ H_2O, 298.15\ K) = -76.78$ kcal·mol^{-1}.[4]

Petersen[5] measured the enthalpy of precipitation of SrF_2 from an aqueous $SrCl_2$ solution with AgF(aq) as $\Delta H - 34.5$ kcal·mol^{-1} at 293 K. We estimate a $\Delta C_p° = 108$ cal K^{-1}·mol^{-1} for $2(AgF \cdot 200\ H_2O) + SrCl_2 \cdot 400\ H_2O + SrF_2$(cr) + 2 AgCl(cr) which gives $\Delta H(298.15\ K) = -34.0$ kcal·mol^{-1}. This value leads to $\Delta_f H°(SrF_2, cr, 298.15\ K) = -290.9$ kcal·mol^{-1} when combined with the following enthalpies of formation: $\Delta_f H°(AgCl, cr, 298.15\ K) = -30.37$[6] $\Delta_f H°(AgF \cdot 200\ H_2O, 298.15\ K) = -53.398$[6] and $\Delta_f H°(SrCl_2 \cdot 400\ H_2O, 298.15\ K) = -209.871$ kcal·mol^{-1}.[3]

Stephen and Stephen[7] have selected as a "best" value for the solubility of SrF_2 0.119 g/l at 298.15 K which corresponds to $K_{sp} = 3.397 \times 10^{-9}$. Using $\Delta_f G°(Sr^{+2}, aq\ \infty, 298.15\ K) = -133.71$[3] and $\Delta_f G°(F^-, aq\ \infty, 298.15\ K) = -66.96$ kcal·mol^{-1},[4] we calculate $\Delta_f G°(SrF_2, cr, 298.15\ K) = -279.18$ kcal·mol^{-1}. Based on the adopted functions for SrF_2, this value gives $\Delta_f H°(SrF_2, cr, 298.15\ K) = -291.5$ kcal·mol^{-1}.

Very recently, Finch *et al.*[9] measured the enthalpy of precipitation of SrF_2 from an aqueous $SrCl_2$ solution by addition of a slight excess of NaF. X-ray diffraction patterns showed the precipitate to be crystalline SrF_2. Reduction of their data gives $\Delta_{sln} H° = 0.42$ kcal·mol^{-1} for SrF_2(cr) $\rightarrow Sr^{+2}$(aq ∞) + 2 F^-(aq ∞) from which we obtain $\Delta_f H°(SrF_2, cr, 298.15\ K) = -290.5 \pm 0.5$ kcal·mol^{-1} with $\Delta_f H°(Sr^{+2}, aq\ \infty, 298.15\ K) = -130.45$[3] and $\Delta_f H°(F^-, aq\ \infty, 298.15\ K) = -79.82$ kcal·mol^{-1}.

The adopted enthalpy of formation, $\Delta_f H°(SrF_2, cr, 298.15\ K) = -290.9 \pm 0.7$ kcal·mol^{-1}, is a weighted value of these four results. Barany *et al.*[8] determined the enthalpy of solution of SrO(cr) in 20.1 wt % aqueous HF, which contained some dissolved silica, as -65.41 ± 0.30 kcal·mol^{-1}. We assume this value refers to the process SrO(cr) + 2 HF ∞ 4.41 $H_2O \rightarrow SrF_2$(cr) + 2 H_2O(l) at 298.15 K, and we calculate $\Delta_f H°(SrF_2, cr, 298.15\ K) = -291.8 \pm 2.0$ kcal·mol^{-1} with $\Delta_f H°(SrO, cr, 298.15\ K) = -141.5$ kcal mol^{-1}).[4] These results substantiate our adopted $\Delta_f H°$ value.

Heat Capacity and Entropy

$C_p°$ below 300 K is based on the low-temperature (11–300 K) heat capacities for SrF_2 reported by Smith *et al.*[10] The sample purity was 99.9% by petrographic examination. We have fitted a smooth polynomial curve through their data and obtained $S°(298.15\ K) = 19.63 \pm 0.05$ cal K^{-1}·mol^{-1} based on S(10.9) = 0.021 cal K^{-1}·mol^{-1}.

The only high temperature enthalpy data is that recently reported by Efremova and Matizen[11] in the temperature range 813–2126 K. Spectroscopic analysis showed the SrF_2 sample contained less than 0.04% of foreign metals. A second order transition was observed between the temperatures of 1421 and 1484 K. We adopt their smoothed $C_p°$ data in the temperature range 900–1750 K; $C_p°$'s above the melting point are obtained by graphical extrapolation. $C_p°$ is assumed constant at 39.5 cal K^{-1}·mol^{-1} over the temperature interval (1421–1484 K) of the transition (see further discussion in Transition Data). The observed enthalpies of Efremova and Matizen[11] deviate from our adopted ones by 1.4% at the lowest temperature (813 K) of their measurements and by only a few tenths of one percent at the higher temperatures.

Transition Data

Efremova and Matizen[11] reported that the phase transition for SrF_2 occurs over a short temperature interval (1421–1484 K). There are no discontinuities in their enthalpy data in this temperature range. Other alkaline earth dihalides[12] which have the calcium fluoride structure, are known to exhibit similar behavior, and this fact would seem to rule out the possibility that the observed transition resulted wholly from impurities. We speculate that the two crystalline forms, α and β, of SrF_2 are practically of the same energy content and can therefore, coexist over this temperature interval.

We choose to tentatively adopt two transitions with zero enthalpies, pending resolution of the phases present at these temperatures by X-ray diffraction measurements. The adopted values are placed in brackets above to emphasize that there is no confirmatory evidence for their existence.

Fusion Data

Refer to the liquid table for details.

Sublimation Data

Refer to the ideal gas table for details.

PREVIOUS: CURRENT: December 1972

$S°(298.15\ K) = [109.445]\ J·K^{-1}·mol^{-1}$
$T_{fus} = 1750 \pm 2\ K$

$\Delta_f H°(298.15\ K) = [-1172.043]\ kJ·mol^{-1}$
$\Delta_{fus}H° = 29.673 \pm 0.628\ kJ·mol^{-1}$

Enthalpy of Formation

$\Delta_f H°(SrF_2, l, 298.15\ K)$ is calculated from $\Delta_f H°(SrF_2, cr, 298.15\ K)$ by adding the enthalpy of fusion, $\Delta_{fus}H°$, and the difference in enthalpy, $H°(1750\ K)-H°(298.15\ K)$, between the crystal and liquid.

Heat Capacity and Entropy

The heat capacity for liquid SrF_2 is obtained from the enthalpy measurements of Efremova and Matizen[1]. $C_p°$ is assumed to be constant in the temperature range 1200–3500 K. At 1200 K a glass transition is assumed below which $C_p°$ follows that of the crystal. The entropy is calculated in a manner analogous to that used for the enthalpy of formation.

Fusion Data

Kojima *et al.*[2] determined the melting point of a SrF_2 sample, which had been purified by passing anhydrous HF through the melt, as 1746 ± 1 K. Porter and Brown[3] found a melting point of 1736 ± 5 K for a sample of 99.8 + % purity, while Petit and Delbove[4] reported 1735 K. The adopted melting point, 1750 ± 2 K, is that determined by Efremova and Matizen[1] in their calorimetric studies of a high purity SrF_2 sample. The enthalpy of melting, 7.092 ± 0.150 $kcal·mol^{-1}$, is calculated as the difference between the adopted enthalpies of the liquid and crystal at T_{fus}.

Vaporization Data

The boiling point is calculated as the temperature at which the fugacity is one atmosphere for the vaporization process. The enthalpy of vaporization is the difference in $\Delta_f H°(T_{vap})$ for the liquid and gas.

$S°(298.15\ K) = 291.715 \pm 2.1\ J\cdot K^{-1}\cdot mol^{-1}$

$\Delta_f H°(0\ K) = -764.053 \pm 4.2\ kJ\cdot mol^{-1}$

$\Delta_f H°(298.15\ K) = -766.090 \pm 4.2\ kJ\cdot mol^{-1}$

Vibrational Frequencies and Degeneracies ν, cm^{-1}
442 (1)
82 (1)
443 (1)

Ground State Quantum Weight: 1 $\sigma = 2$

Point Group: C_{2v}

Bond Distance: Sr–F = 2.20 ± 0.03Å

Bond Angle: F–Sr–F = 108°

Product of the Moments of Inertia: $I_A I_B I_C = 4.022689 \times 10^{-114}\ g^3\cdot cm^6$

Enthalpy of Formation

$\Delta_f H°$ is obtained from that of the crystal by addition of the adopted $\Delta_{sub}H° = 107.8 \pm 0.3\ kcal\cdot mol^{-1}$. 2nd and 3rd law analyses of four sets of vapor pressure data for SrF_2(cr, l) are listed below.

Source	Method	T/K	$\Delta_{sub}H°$(298.15 K), kcal·mol^{-1} 2nd law	3rd law	Drift cal $K^{-1}\cdot mol^{-1}$	$\Delta_f H°$(298.15 K) kcal·mol^{-1}
Ruff and Le Boucher[1]	Dynamic B.P.	2095–2232	106.4[a]	96.1 ± 0.8	−4.8 ± 3.1	−184.0 ± 1.5
Bautista and Margrave[2]	Langmuir	1235–1319	104.5	108.0 ± 0.5	2.8 ± 2.9	−182.9 ± 1.2
Green *et al.*[3]	Knudsen	1207–1563[b]	107.9	107.8 ± 0.3	−0.07 ± 0.38	−183.1 ± 1.0
Hildenbrand[4]	Torsion–Effusion	1420–1710	103.8	106.5 ± 0.4	1.7	−184.4 ± 1.1

[a] $\Delta_{vap}H°(298.15\ K)$

[b] Six of the 30 experimental points were rejected due to failure of a statistical test.

Note that the drifts are both positive and negative indicating the correctness of the functions used in the analysis. A weighted value of these four results is adopted.

Heat Capacity and Entropy

The bond length is that measured by Akishin and Spiridonov [5] in their high–temperature electron diffraction studies of the alkaline earth dihalide vapors. Although it was inferred from these measurements that all the dihalides are linear, recent results of electric–deflection experiments [6] and matrix isolation infrared spectra[1,8] for SrF_2 can only be satisfactorily interpreted in terms of a molecule with a bent configuration. We adopt the vibrational frequencies and bond angle determined by Calder *et al.*[8] in their thorough investigation of the infrared spectra of isotopically enriched samples of SrF_2 trapped in krypton matrices. The uncertainty assigned to the entropy reflects possible errors due to matrix–shift effects in these frequencies. The adopted symmetric (ν_1) and antisymmetric (ν_3) stretching frequencies are in reasonable agreement with those determined by Snelson[7] for SrF_2 trapped in neon, argon, and krypton matrices. Also, the antisymmetric frequency is quite consistent with the value 445 ± 7 cm^{-1} observed by Baikov[9] in the infrared spectra of SrF_2 vapor at 2050 K. In an earlier paper, Baikov[10] reported observing under similar conditions a broad absorption band at 105 cm^{-1} which he assigned to the symmetric bending (ν_2) mode of SrF_2. We prefer the matrix value (82 cm^{-1}, since Baikov[10] recorded only the high–frequency (>90 cm^{-1}) portion of this band. Furthermore, Hastie *et al.*[11] have pointed out that, in general, bending frequencies are less influenced by matrix effects and in some cases may be shifted slightly upwards from the gas phase values.

The individual moments of inertia are: $I_A = 7.3594 \times 10^{-39}$, $I_B = 19.9877 \times 10^{-39}$, and $I_C = 27.3471 \times 10^{-39}\ g\cdot cm^2$.

Enthalpy of Formation

Zmbov and Margrave[1] have reported ion intensities and the corresponding equilibrium constants for the reaction $Ca(g) + TiF_3(g) = CaF(g) + TiF_2(g)$. 2nd and 3rd law analyses of their data give a 2nd law $\Delta_r H°(298.15\ K)$ of 7.0 $kcal \cdot mol^{-1}$, a 3rd law $\Delta_r H°(298.15\ K)$ of 11.76 $kcal \cdot mol^{-1}$, and a 3rd law drift of 3.1 ± 3.8 $cal\ K^{-1} \cdot mol^{-1}$. The enthalpy of formation, $\Delta_f H°(298.15\ K)$, of $TiF_2(g)$ is calculated from the 3rd law $\Delta_r H°(298.15\ K)$, above, and the JANAF enthalpies of formation of $TiF_3(g)$, CaF(g) and Ca(g).

Heat Capacity and Entropy

The interatomic distances are estimated from those of $TiCl_2$, $TiCl_4$, and TiF_4. The vibrational frequencies are estimated from a valence force field model.

The electronic levels are assumed to be the same as $TiCl_2(g)$. The levels of $TiCl_2(g)$ are estimated by assuming they correspond to the inverted states of $NiCl_2(g)$.[2] The linear configuration is assumed because experimental evidence[3] indicates that other transition metal difluorides, viz those of Mn, Co, Ni, Cu, and Zn, are linear.

PREVIOUS: December 1968 (1 atm) CURRENT: December 1968 (1 bar)

$S°(298.15\ K) = [75.312 \pm 8.4]\ J \cdot K^{-1} \cdot mol^{-1}$
$T_{fus} = [1175 \pm 150]\ K$

$\Delta_f H°(298.15\ K) = [-962.320 \pm 63]\ kJ \cdot mol^{-1}$
$\Delta_{fus} H° = [38 \pm 8]\ kJ \cdot mol^{-1}$
$\Delta_{sub} H°(298.15\ K) = [404.174]\ kJ \cdot mol^{-1}$

Enthalpy of Formation

The adopted $\Delta_f H°(ZrF_2, cr, 298.15\ K)$ value is taken from NBS[1] which was estimated by Brewer.[2] More recent thermal data related to the enthalpy of formation of ZrF_2(cr) is unavailable.

Heat Capacity and Entropy

The heat capacities in the temperature range 298–2000 K are estimated by comparison with those of ZrF_4(cr) and Zr(cr). The $S°(298.15\ K)$ is calculated as 17.2 and 17.0 cal $K^{-1} \cdot mol^{-1}$ based on the assumptions that $S(ZrF_2) = 1/2[S(ZrF_4) + S(Zr)]$ and $S(ZrF_2) = S(ZnF_2) - S(Zn) + S(Zr)$. Using the additive entropy constants $S°(298.15\ K) = 12.1$ and 4.7 cal $K^{-1} \cdot mol^{-1}$ for Zr and F suggested by Kubaschewski and Evans[3] we obtain $S°(ZrF_2, cr, 298.15\ K) = 12.1 + 2\ (4.7) = 21.5$ cal $K^{-1} \cdot mol^{-1}$. Based on $S°(298.15\ K) = 11.5$ and 3.9 cal $K^{-1} \cdot mol^{-1}$ for Zr^{4+} and F^- recommended by Kelley,[4] the value $S°(ZrF_2, cr, 298.15\ K)$ is derived as 19.3 cal $K^{-1} \cdot mol^{-1}$. The entropy at 298 K for ZrF_2(cr) is tentatively adopted as 18 ± 2 cal $K^{-1} \cdot mol^{-1}$.

Sublimation Data

The difference between $\Delta_f H°(298.15\ K)$ for ZrF(g) and ZrF_2(cr) is $\Delta_{sub} H°(298.15\ K)$.

$S°(298.15\ K) = [100.846]\ J·K^{-1}·mol^{-1}$
$T_{fus} = [1175 \pm 150]\ K$

$\Delta_f H°(298.15\ K) = [-936.951]\ kJ·mol^{-1}$
$\Delta_{fus}H° = [38 \pm 8]\ kJ·mol^{-1}$

Enthalpy of Formation

$\Delta_f H°(ZrF_2, l, 298.15\ K)$ is calculated from $\Delta_f H°(ZrF_2, cr, 298.15\ K)$ by adding the enthalpy of fusion, $\Delta_{fus}H°$, and the difference in enthalpy, $H°(1175\ K)-H°(298.15\ K)$, between the crystal and liquid.

Heat Capacity and Entropy

The heat capacity is estimated from those of $ZrF_4(l)$, $CaF_2(l)$, Zr(l) and Ca(l) and is assumed to be constant in the temperature range 800–3000 KA glass transition temperature is assumed at 800 K. The $C_p°$ values below 800 K are adopted from the ZrF_2(cr) table. The entropy is calculated in a manner analogous to that used for the enthalpy of formation.

Fusion Data

Both T_{fus} and $\Delta_{fus}H°$ are estimated. The derived entorpy of melting, 2.55 cal $K^{-1}·mol^{-1}$/atom, is the same as that of ZrF_4(cr) which was obtained from experimental measurements.[1] Therefore these estimated values are tentatively adopted.

Vaporization Data

The boiling point, T_{vap}, is calculated as the temperature at which the fugacity is one atmosphere for the process $ZrF_2(l) = ZrF_2(g)$.

Enthalpy of Formation

Murad and Hildenbrand[1] studied the gaseous equilibria involving ZrF_4, ZrF_3, ZrF_2, Ca, and CaF, mass-spectrometrically. Ion intensities were measured 3 cal $K^{-1}·mol^{-1}$ above threshold over the temperature range 1665–1747 K, and the equilibrium constants for the reaction 2 Ca(g) + ZrF_4(g) = 2 CaF(g) + ZrF_2(g) were calculated. Using the reported equilibrium constants, the enthalpy changes $\Delta_r H°(298.15\ K)$ of this reaction are evaluated by the 2nd and 3rd law methods to be 15.4 and 50.9 kcal·mol^{-1}, respectively. The drift in 3rd law values is 20.4 ± 17.6 cal $K^{-1}·mol^{-1}$. Based on the 3rd law $\Delta_r H°(298.15\ K)$ value and $\Delta_f H°(298.15\ K) = 42.85 \pm 0.3$, -65.0 ± 2, and -400.0 ± 0.5 kcal·mol^{-1} for Ca(g), CaF(g), and ZrF_4, respectively, we obtain $\Delta_f H°(ZrF_2, g, 298.15\ K) = -133.4 \pm 5$ kcal·mol^{-1}(-558.146 ± 20.9 kJ·mol^{-1}) which is adopted.

Using Gibbs energy functions derived from different molecular constants for the reactants and products, Murad and Hildenbrand[1] derived a 3rd law $\Delta_r H°(298.15\ K) = 42.6 \pm 5$ and $\Delta_f H°(ZrF_2, g, 298.15\ K) = -141 \pm 5$ kcal·mol^{-1}, which are in fair agreement with the adopted values.

Heat Capacity and Entropy

According to the correlations of Charkin and Dyatkina,[2] the ZrF_2(g) molecule has an angular configuration. The F–Zr–F angle is estimated at 125°, which is similar to the value reported by Hastie *et al.*[4] for TiF_2(g). The F–Zr bond distance is estimated from that of ZrF_4(g). The vibrational frequencies are calculated based on the method suggested by Herzberg.[3] The value ν_1 is calculated from the vibrational frequency (ν) of ZrF(g) by use of the relation $\nu_1 = \nu[Zr/(Zr+F)]^{1/2}$ where Zr and F are gram atomic weights of zirconium and fluorine. ν_3 is derived from ν_1 using the formula $\nu_3 = \nu_1[(Zr_1+2F)/Zr]^{1/2}$ and ν_2 is calculated as 0.44 ν_3 where the value 0.44 is estimated by comparison with the ratios of ν_2/ν_3 or other related compounds. Ground state quantum weight is taken to be the same as that of TiF_2(g). The three principal moments of inertia are: $I_A = 3.5010 \times 10^{-39}$, $I_B = 18.3005 \times 10^{-39}$, and $I_C = 21.8015 \times 10^{-39}$ g·cm^2. The electronic levels and quantum weights are estimated to be the same as those of TiF_2(g).

PREVIOUS: December 1969 (1 atm) CURRENT: December 1969 (1 bar)

$S°(298.15\ K)$ = [98.324 ± 8.4] $J·K^{-1}·mol^{-1}$

$\Delta_f H°(0\ K)$ = Unknown

$\Delta_f H°(298.15\ K)$ = −1041.816 ± 12.6 $kJ·mol^{-1}$

Enthalpy of Formation

The equilibrium pressures for the reaction 2 FeF_3(cr) + H_2(g) = 2 FeF_2(cr) + 2 HF(g) have been measured at temperatures 623, 723, and 823 K by Jellinek and Rudat.[1] Using the reported data, the enthalpy change of the reaction was evaluated as 37.9 and 31.3 $kcal·mol^{-1}$ by the 3rd and 2nd law, respectively. The corresponding $\Delta_f H°$(FeF_3, cr, 298.15 K) values are calculated to be −252.4 and −249.2 $kcal·mol^{-1}$. The equilibrium constants for the reaction 2 FeF_3(cr) + 3 H_2O(g) = Fe_2O_3(cr) + 6 HF(g) were determined by Domange.[2] Based on the 3rd law value of $\Delta_r H°$(298.15 K), 62.0 $kcal·mol^{-1}$, the $\Delta_f H°$(FeF_3, cr, 298.15 K) was calculated as −237.4 $kcal·mol^{-1}$. The value of $\Delta_f H°$(298.15 K) for FeF_3(cr) is selected to be −249 ± 3 $kcal·mol^{-1}$.

Heat Capacity and Entropy

The heat capacities of FeF_3(cr) at temperatures 100–450 K were determined by Bizette *et al.*[3] The results were presented graphically by plotting $C_p°$ vs T. The $C_p°$ curve shows a peak at 367 K. An antiferromagnetic transition at about 394 K was reported by Wollan *et al.*[4] The heat capacities above 450 K and $S°$(298.15 K) were estimated by comparison with those for $FeCl_3$(cr), $AlCl_3$(cr) and AlF_3(cr).

Sublimation Data

The phenomenon that FeF_3(cr) sublimes without fusion at temperatures near 1000°C has been observed and reported by Poulenc.[5] Based on this data, the value of T_{sub} was estimated. The value of heat of sublimation, $\Delta_{sub}H°$(298.15 K), is calculated using an estimated entropy of sublimation, $\Delta_{sub}S°$ = 40 cal $K^{-1}·mol^{-1}$ in order to have $\Delta_r G°$(1200 K) = 0 for the reaction FeF_3(cr) = FeF_3(g).

[250](1)	[220](2)

Ground State Quantum Weight: [1] σ = [6]
Point Group: [D_{3h}]
Bond Distance: Fe–F = [1.9] Å
Bond Angle: F–Fe–F = [120]°
Product of the Moments of Inertia: $I_A I_B I_C$ = [9.971132 × 10^{-114}] $g^3·cm^6$

Enthalpy of Formation

The value of $\Delta_f H°(FeF_3, g, 298.15\ K)$ is calculated from $\Delta_{sub}H°(298.15\ K)$ and $\Delta_f H°(298.15\ K)$ for FeF_3(cr). The value $\Delta_{sub}H°(298.15\ K)$ = 65.5 $kcal·mol^{-1}$ is derived from $\Delta_{sub}H°(1200\ K)$. Refer to the crystal table for details.

Heat Capacity and Entropy

The molecular structure, bond distance and angle are estimated by comparison with those for AlF_3(g). The vibrational frequencies are estimated by comparison with those for AlF_3(g), TiF_3(g) and ZrF_3(g). The three principal moments of inertia are: $I_A = I_B$ = 17.0833 × 10^{-39} and I_C = 34.1666 × 10^{-39} $g·cm^2$.

Ground State Quantum Weight: [1] $\sigma = 3$
Point Group: C_{3v}
Bond Distances: Si–H = 1.4468 Å; Si–F = 1.5624 Å
Bond Angles: H–Si–F = 110.64°; F–Si–F = 108.28°
Product of the Moments of Inertia: $I_A I_B I_C = 2.726959 \times 10^{-114}\ g^3 \cdot cm^6$

Enthalpy of Formation

There are no reported experimental studies leading to the enthalpy of formation of $SiHF_3(g)$. We estimate this value via a linear interpolation between the established $\Delta_f H°(298.15\ K)$ values of $SiH_4(g)$ and $SiF_4(g)$.[1] The reasonableness of this approach has been demonstrated by Lapidus *et al.*,[2] Hunt and Sirtl,[3] and Seiter and Sirtl.[4] Lapidus *et al.*[2] comparatively examined the thermodynamic properties of halogenated silanes and methanes. Hunt and Sirtl[3] and Seiter and Sirtl[4] studied the chlorinated silanes and proposed a linear $\Delta_f H°$ relationship within the sequence $SiH_4(g)$ to $SiCl_4(g)$.

Heat Capacity and Entropy

The adopted vibrational frequencies are from the infrared gas phase studies of Buerger *et al.*[5,6] These values are all within $\pm 1\ cm^{-1}$ of the suggested values in the compilation by Shimanouchi,[7] as derived from Newman *et al.*[8]

The adopted bond angles and bond distances are obtained from the microwave spectrum study of six isotopic species of $HSiF_3$.[9] Earlier work by Sheridan and Gordy[11] and Heath *et al.*[11] is in good agreement with these values. The moments of inertia are calculated to be $I_A = I_B = 11.6094 \times 10^{-39}\ g\ cm^2$ and $I_C = 20.2329 \times 10^{-39}\ g \cdot cm^2$.

Ground State Quantum Weight: 1 σ = [3]
Point Group: C_3
Interatomic Distance: F–F = [2.5] Å
Product of the Moments of Inertia: $I_A I_B I_C = [2.237956 \times 10^{-114}]\ g^3·cm^6$

Enthalpy of Formation

The enthalpy of 3 HF(g) → H_3F_3(g) was taken as the mean of 3rd law values which were determined from the equilibrium data of two investigations. Briegleb and Strohmeier[1] measured the vapor density of HF between 20 and 60°C and between 50 and 650 torr. Franck and Meyer[2] measured $C_p°$ between −20 and 100°C and between 100 and 700 torr. Each investigation evaluted K_p at n = 2, 3, 4, ... for the reactions n(HF) → $(HF)_n$ and reported 2nd law values of $\Delta_r H°$ and $\Delta_r S°$. At $n = 3$, their 2nd law values differed by 2.7 $kcal·mol^{-1}$ which was taken as an estimate of error, while the 3rd law values differed by 0.20 $kcal·mol^{-1}$. Using $\Delta_r H°(298.15\ K) = -14.69\ kcal·mol^{-1}$ and auxiliary JANAF data[3] gives the enthalpy of formation of H_3F_3(g).

Heat Capacity and Entropy

The molecular structure of H_3F_3 was assumed as planar with the F atoms forming the vertices of a regular triangle and with the H atoms also lying on the circumscribed circle. That rings are more stable than open chains was confirmed by Del Bene and Pople's[4] theoretical molecular-orbital studies on HF polymers. The length of side (F-F axis) was taken from Atoji and Lipscomb's[5] X-studies of solid HF (F−F = 2.49 Å) and agrees with 2.52 Å which Janzen and Bartell[6] determined for HF gaseous polymers by electron diffraction. Vibrational frequencies were taken from Kittelberger and Hornig's[7] work on crystalline HF. Huong and Couzi[8] and Smith[9] have made spectral studies of the gas phase in the range from 350 to 4000 cm^{-1}.

The National Bureau of Standards prepared this table[10] by critical analysis of data existing in 1972. Using molecular constants and $\Delta_f H°$ selected by NBS,[10] we recalculate the table in terms of 1973 fundamental constants,[11] 1975 atomic weights,[12] and current JANAF reference states for the elements.

Ground State Quantum Weight: [1] $\sigma = 6$
Point Group: [D_{3h}]
Bond Distance: Li–F = [1.68] Å
Bond Angles: F–Li–F = [120]°; Li–F–Li = [120]°
Product of the Moments of Inertia: $I_A I_B I_C = [1.212852 \times 10^{-113}]\ g^3 \cdot cm^6$

Enthalpy of Formation

$\Delta_f H°(Li_3F_3, g, 298.15\ K)$ is derived based on the adopted value $\Delta_r H°(298.15\ K) = 79.73\ kcal \cdot mol^{-1}$ for the reaction $3LiF(cr) = Li_3F_3(g)$, using $\Delta_f H(LiF, cr, 298.15\ K) = -147.45\ kcal \cdot mol^{-1}$. The $\Delta_r H°(298.15\ K)$ value is calculated to be 73.9 $kcal \cdot mol^{-1}$ at 1000 K, which is consistent with the values $\Delta_s H°(1000\ K) = 73.9 \pm 3$ and $74.9 \pm 1\ kcal \cdot mol^{-1}$ reported by Buchler and Stauffer[1] and Akishin *et al.*,[2] respectively. Using the adopted $\Delta_f H°(298.15\ K)$ values for monomer, dimer, and trimer, we also evaluate the value $\Delta_r H°(1073\ K) = 53.8\ kcal \cdot mol^{-1}$ for the reaction $Li_3F_3(g) = Li_2F_2(g) + LiF(g)$ which is in agreement with the value $50 < \Delta_r H°(1073\ K) < 65\ kcal \cdot mol^{-1}$ reported by Porter and Schoonmaker.[3] Rothberg *et al.*[4] have determined the partial pressures of LiF monomer, dimer, and trimer in the temperature range 980–1070 K, using the molecular-beam velocity-selector method.[5] However, the total pressures derived from these data are too low in comparison with the other reported vapor pressures. Thus their data are not adopted for evaluation.

Heat Capacity and Entropy

The molecular structure is assumed to be the same as that of the BeO trimer. The Li–F bond distance is taken from that of the Li_2F_2 molecule determined by Akishin and Rambidi.[6] Four vibrational frequencies, A_2'' and three E', are reported by Snelson[7] from analysis of the infrared spectra of LiF Using the matrix isolation technique. The reported frequencies are corrected to the average isotopic species. The other four frequencies, E_2'' and three A', are estimated by comparison with those for the isoelectronic molecule Be_3O_3. The three principal moments of inertia are: $I_A = I_B = 18.2358 \times 10^{-39}$ and $I_C = 36.4717 \times 10^{-39}\ g \cdot cm^2$.

Ground State Quantum Weight: [2] σ = [6]
Point Group: D_{3h}
Bond Distance: Mo–F = [1.82] Å
Bond Angle: F–Mo–F = [120]°
Product of the Moments of Inertia: $I_A I_B I_C = [7.702846 \times 10^{-114}]\ g^3 \cdot cm^6$

Enthalpy of Formation

The adopted enthalpy of formation at 298.15 K is that derived by Brewer[1] from the high temperature mass spectrometric measurements of equilibria among gaseous molybdenum fluorides by Hildenbrand [1664 and 2146 K][2] and among gaseous and hetrogeneous phases by Alikhanyan *et al.* [911 and 964 K].[3] The value of $\Delta_f H°(0\ K)$ combined with JANAF data[4] for Mo(g) and F(g) gives $\Delta_{at} H°(0\ K) = 356.5 \pm 6$ kcal·mol^{-1} and an average Mo–F bond energy of $\Delta_{at} H°(0\ K)/3 = 118.8 \pm 2$ kcal·mol^{-1}.

Heat Capacity and Entropy

We use the vibrational frequencies and degeneracies estimated by Hildenbrand[2] and adopted by Brewer.[1] The correlation of Drake and Rosenblatt[5] leads to a planar configuration for MoF_3(g). The Mo–F distances of 1.82 Å from MoF_6(g) is used. The observed electronic levels[4] of the isoelectronic TaO(g) are assumed, as suggested by Brewer,[1] up through 11062 cm^{-1}. The principal moments of inertia are: $I_A = I_B = 15.6750 \times 10^{-39}$ and $I_C = 31.3500 \times 10^{-39}$ g·cm^2.

This table is based on the critical analysis of data existing in 1978 by Brewer.[1]

Enthalpy of Formation

The adopted enthalpy of formation is the mean of values calculated from the reaction processes listed below and weighted inversely as the squares of the standard deviations. Auxiliary enthalpies of formation were taken from NBS [1] or from simultaneous adjustment of several interconnecting pieces of data.[2] Also given below are the references, individual and averaged measured values of enthalpies of reaction and their uncertainties, the value of enthalpy of formation calculated from each process and its uncertainty, and the weighted mean.

Heat Capacity and Entropy

The vibrational frequencies are from the infrared studies of Schatz and Levin [10] and are in good agreement with those of Pace and Pierce,[11] and Wilson and Polo.[12] The adopted values are also in agreement with the Raman studies of Kotov and Tatevskii.[13] The bond length and angle are from the microwave studies of Sheridan and Gordy,[14] whose values are in substantial agreement with the electron diffraction results of Schomaker and Lu.[15]

The principal moments of inertia are $I_A = I_B = 7.8554 \times 10^{-39}$ g cm^2 and $I_C = 14.3560 \times 10^{-39}$ g·cm^2.

Pierce and Pace [16] have obtained the entropy of the gas at 144.15 K from solid heat capacity measurements and the heats of melting and vaporization. Their reported value of 54.50 cal $K^{-1} \cdot mol^{-1}$ is in good agreement with our calculated value of 54.56 cal $K^{-1} \cdot mol^{-1}$.

The National Bureau of Standards prepared this table [17] by critical analysis of data existing in 1972. Using molecular constants and $\Delta_f H°$ selected by NBS,[17] we recalculate the table in terms of 1973 fundamental constants,[18] 1975 atomic weights,[19] and current JANAF reference states for the elements.

Enthalpy of Formation

Bougon *et al.*[1] determined equilibrium constants for the reaction NOF(g) + F_2(g)⇆NOF_3(g) as a function of temperature and total pressure. 2nd and 3rd law analyses of these equilibrium data are given below:

	Data Points	T/K	$\Delta_f H°$(298.15 K), kcal·mol^{-1} 2nd law	3rd law	Drift cal $K^{-1} \cdot mol^{-1}$
Set I	7	533–643	−17.1	−18.7	−2.4 ± 2.1
Set II	1	533.2		−18.2	

Set I contains their equilibrium data as a function of temperature, while Set II is their adopted equilibrium constant, $K_p°$ (553.2 K) = 0.015 ± 0.005 atm^{-1}, corresponding to the lowest pressure (103 atm.) that was studied. Estimated corrections for nonideality are small and neglected. Adopting $\Delta_f H°(298.15\ K) = -18.7 \pm 1.0\ kcal \cdot mol^{-1}$, we derive $\Delta_f H°(NOF_3, g, 298.15\ K) = -34.4 \pm 1.4\ kcal \cdot mol^{-1}$ with $\Delta_f H°(NOF, g, 298.15\ K) = -15.7 \pm 0.4\ kcal \cdot mol^{-1}$.[2]

Armstrong and King [3] determined $\Delta_r H°(304\ K) = -253.7 \pm 0.6\ kcal \cdot mol^{-1}$ for the reaction $NOF_3(g) + 5/2\ H_2(g) + 122\ H_2O(l) \rightarrow 1/2\ N_2(g) + [3\ HF123 \cdot H_2O](l)$ in a constant pressure flame calorimeter. Combining this result with their earlier enthalpy data for reduction reactions involving F_2(g) and O_2(g) with H_2(g), they obtained $\Delta_f H°(NOF_3, g, 304\ K) = -44.7 \pm 1.5\ kcal \cdot mol^{-1}$.

Very recently, Dibeler and Walker[4] investigated the photoionization of NOF_3 by mass spectrometry. From their ionization threshold data, they determined $\Delta_f H°(NOF_3, g, 0\ K) = -69.6 \pm 1.2\ kcal \cdot mol^{-1}$.

The value for the enthalpy of formation of gaseous NOF_3 is tentatively selected as $-39.0 \pm 5.0\ kcal \cdot mol^{-1}$.

Heat Capacity and Entropy

Several recent infrared[5,6,7] and Raman[8] studies of NOF_3 have been reported in the literature. The fundamental vibrational frequencies observed in the infrared spectrum of the molecule by the various investigators are in good agreement, although the assignment of the ν_3 and ν_5 bending modes has varied. Fox *et al.*[6] assigned $\nu_3 = 558\ cm^{-1}$ and $\nu_5 = 528\ cm^{-1}$, while Curtis *et al.*[7] reversed the assignments. Very recently, Abramowitz and Levin[8] investigated the Raman spectrum of polycrystalline film of NOF_3 at 78 K and assigned $\nu_3 = 535\ cm^{-1}$ and $\nu_5 = 522\ cm^{-1}$ consistent with the infrared work of Fox *et al.*[6] The fundamental vibrational frequencies and assignments given by Fox *et al.*[6] are adopted here.

Fox *et al.*[9] also investigated the nuclear magnetic resonance spectrum of NOF_3 which indicated that the molecule contained three equivalent fluorine atoms. This result, along with the general appearance of the infrared spectrum, clearly establishes that the molecule has C_{3v} symmetry. The N–O bond distance and bond angles are estimated quantities from the work of Curtis *et al.*[7] These estimated data have been used in calculating the N–F bond distance from the rotational constants given by Curtis *et al.*[7] Individual moments of inertia calculated from the structural data given above are: $I_A = I_B = 14.8502 \times 10^{-39}$ and $I_C = 18.4285 \times 10^{-39}\ g \cdot cm^2$.

Ground State Quantum Weight: [1] $\sigma = 3$

Point Group: C_{3v}

Bond Distances: P–O = 1.45 ± 0.03 Å; P–F = 1.52 ± 0.02 Å

Bond Angles: F–P–F = 102.5 ± 2°; F–P–O = 115.8 ± 2°

Product of the Moments of Inertia: $I_A I_B I_C = 5.907318 \times 10^{-114}\ g^3 \cdot cm^6$

Enthalpy of Formation

Ebel and Bretscher[1] measured the enthalpy change for the following reaction: $PF_3(g) + 1/2\ O_2(g) \rightarrow POF_3(g)$. They reported a heat of reaction of $-70.6 \pm 1\ kcal \cdot mol^{-1}$. Combining this result with the enthalpy of formation of PF_3, $\Delta_f H°(298.15\ K) = -224.9 \pm 0.9\ kcal \cdot mol^{-1}$,[2] we derive, $\Delta_f H°(POF_3, g, 298.15\ K) = -295.6 \pm 1.9\ kcal \cdot mol^{-1}$.

Heat Capacity and Entropy

The vibrational frequencies are from the infrared studies of Selig and Claasen[3] and are in good agreement with the Raman and infrared studies of Gutowsky and Liehr.[4] Several microwave studies[5,6,7,8] of POF_3 have been reported. As pointed out by Williams *et al.*,[7] the rotational constant calculated from their microwave studies leads to a moment of inertia, I_B, which is in disagreement with the moment of inertia calculated from the molecular constants obtained from electron-diffraction studies by Brockway and Beach.[9] Since insufficient microwave data were available for an independent determination, Williams *et al.*[7] sought to find parameters which were consistent with both measurements. Their molecular constants are adopted for this tabulation. Individual moments of inertia are $I_A = 17.7329 \times 10^{-39}$, $I_B = I_C = 18.2518 \times 10^{-39}\ g \cdot cm^2$.

Bond Distances: P–F = 1.5700 ± 0.0012 Å; F....F = 2.3643 ± 0.0028 Å

Bond Angle: F–P–F = 97.8 ± 0.2°

Product of the Moments of Inertia: $I_A I_B I_C = 2.070369 \times 10^{-114}\ g^3 \cdot cm^6$

Enthalpy of Formation

Berthelot[1] measured the enthalpy of hydrolysis of PF_3(g) and PCl_3(l). These results can be combined to give, $\Delta_r H° = 24.5\ kcal \cdot mol^{-1}$ for the reaction

$$PF_3(g) + 3\ KCl \cdot 157\ H_2O \rightarrow PCl_3(l) + 3\ KF \cdot 112\ H_2O.$$

Combining this result with the following enthalpy of formation data,

$\Delta_f H°(PCL_3, l, 298.15\ K) = -72.2\ kcal \cdot mol^{-1}$ [2]

$\Delta_f H°(KCl \cdot 157\ H_2O, 298.15\ K) = -100.0\ kcal \cdot mol^{-1}$ [3]

$\Delta_f H°(KF \cdot 112\ H_2O, 298.15\ K) = -138.5\ kcal \cdot mol^{-1}$ [3]

we derive, $\Delta_f H°(PF_3, g, 298.15\ K) = -212.2\ kcal \cdot mol^{-1}$.

Duus and Mykytink [4] reported an enthalpy of reaction of −2.361 $kcal \cdot mol^{-1}$ (corrected to 25°C) for the following reaction

$$PCl_3(g) + 3/2\ CaF_2(cr) \rightarrow PF_3(g) + 3/2\ CaCl_2(cr).$$

Combining this result with the following enthalpy of formation data,

$\Delta_f H°(PCl_3, g, 298.15\ K) = -64.4\ kcal \cdot mol^{-1}$ [2]

$\Delta_f H°(CaF_2, cr, 298.15\ K) = 293.0 \pm 1.5\ kcal \cdot mol^{-1}$ [5]

$\Delta_f H°(CaCl_2, cr, 298.15\ K) = -190.0\ kcal \cdot mol^{-1}$ [3]

we derive, $\Delta_f H°(PF_3, g, 298.15\ K) = -221.9\ kcal \cdot mol^{-1}$.

Recently, Rudzitis *et al.* [6] measured the enthalpy of combustion of PF_3 in fluorine in a two-chambered bomb calorimeter at 25°C. They reported an enthalpy of combustion of $-152.0 \pm 0.2\ kcal \cdot mol^{-1}$ for the reaction

$$PF_3(g) + F_2(g) \rightarrow PF_5(g).$$

Combining this result with $\Delta_f H°(PF_5, g, 298.15\ K) = -376.9 \pm 0.7\ kcal \cdot mol^{-1}$,[5] we derive $\Delta_f H°(PF_3, g, 298.15\ K) = -224.9 \pm 0.9\ kcal \cdot mol^{-1}$. This result is adopted for this tabulation.

Heat Capacity and Entropy

The vibrational frequencies are those reported by Wilson and Palo.[8] Several different values for the P–F bond length and F–P–F bond angle have been reported in the literature. This problem was recently discussed by Morino *et al.*[9] who also reported new data obtained from electron–diffraction studies. Their results are adopted for this tabulation. Individual moments of inertia calculated according to their structure are: $I_A = I_B = 10.8265 \times 10^{-39}$ and $I_C = 17.6633 \times 10^{-39}\ g \cdot cm^2$.

Enthalpy of Formation

The enthalpy of formation of PSF_3 is calculated from the enthalpy of formation of POF_3 and estimated P=O and P=S bond strengths. Mortimer[1] calculated several P=O and P=S bond dissociation energies from enthalpy of reaction data reported in the literature. Some of these data are given below.

Reaction	D(P=O)	D(P=S)
	kcal·mol^{-1}	
ΔH oxidation PF_3 to POF_3	130.3	
ΔH oxidation $P(OEt)_3$ to $PS(OEt)_3$		81.6
ΔH oxidation PPr_3 to $PSPr_3$		82.6

Mole and McCoubrey[2] reported the following enthalpy of reaction:

$$PCl_3(l) + Si(cr) \rightarrow PSCl_3(l).\ \Delta_r H = -5.6\ kcal\cdot mol^{-1}.$$

Combining this result with enthalpy of vaporization data for PCl_3[3] and $PSCl_3$,[4] along with the enthalpy of sublimation of S,[3] we derive $D(P=S) = 71\ kcal\cdot mol^{-1}$. Averaging this result with the two values given above, we obtain $D(P=S) = 78.4\ kcal\cdot mol^{-1}$. We assume that this result represents the enthalpy change for reaction $PSF_3(g) \rightarrow PF_3(g) + S(g)$. Combining this result with similar data for POF_3, namely $D(P=O) = 130.3\ kcal\cdot mol^{-1}$ and $\Delta_f H°(POF_3, g, 298.15\ K) = -295.6 \pm 1.9\ kcal\cdot mol^{-1}$,[3] we derive $\infty_f H°(PSF_3, g, 298.15\ K) = -237 \pm 15\ kcal\cdot mol^{-1}$, from the relationship $\infty_f H°(PSF_3, g, 298.15\ K) = \infty_f H°(POF_3, g, 298.15\ K) + \infty_f H°(S, g, 298.15\ K) - \infty_f H°(O, g, 298.15\ K) - D(P=O) + D(P=S)$.

Heat Capacity and Entropy

Several recent infrared and Raman studies[7, 8, 9, 10] of PSF_3 have been reported. These data are in good agreement, except for the τ_1 fundamental. Dewaulle and Francois[11] assigned this fundamental to the 869 cm^{-1} band observed in their spectra. The recent work indicates that this fundamental should be assigned to the 981 cm^{-1} band. Average values of the vibrational frequencies reported by[8, 9, 10] are adopted for this tabulation. The molecular structure of this molecule was determined by Williams *et al.*[12] and Hawkins and Cohen[13] from microwave studies. The individual moments of inertia calculated from the constants given by Williams *et al.*[12] are $I_A = 1.74111 \times 10^{-39}$, $I_B = I_C = 31.5349 \times 10^{-39}\ g\cdot cm^2$.

Enthalpy of Formation

$\Delta_f H°$(0 K) = −119.26 ± 8.0 kcal·mol^{-1} is calculated from the primary bond dissociation energy for SF_4 of $D_0°$ (SF_3−F) = 80.0 ± 3.0 kcal·mol^{-1} with JANAF[1] $\Delta_f H°$ data for F(g) and SF_4(g). The value of $D_0°$ is taken to be equal to one-fourth the enthalpy of atomization of SF_4.[1] We calculate the heat of atomization, $\Delta_{at}H°$(0 K), and mean bond dissocation energy ($D_0°$) for SF_3 to be 240.1 kcal·mol^{-1} and 80.0 kcal·mol^{-1}, respectively. $\Delta_f H°$ is −120.227 kcal·mol^{-1} at 298.15 K.

Several pieces of information are available which are relatively imprecise but do support our assumption that $D_0°$ (SF_3−F) = $\Delta_{at}H°$(SF_4)/4. Bott[2] has reported the results of shock-tube experiments on the dissociation of SF_4 over the temperature range 1650–1950 K. Rate constants based on spectroscopic measurements were correlated with the Rice–Ramsperger–Kassel (RRK) theory. This study strongly suggests that $D_0°$ (SF_3−F) = 79.0 ± 3.0 kcal·mol^{-1}.

Electron–impact threshold measurements for SF_3^+ from SF_4 have been reported by Hildenbrand[3] and Glemser *et al.*[4] The measured appearance potentials (AP) are in good agreement and indicate AP(SF_3^+/SF_4) = 12.67 ± 0.1 eV. Combining this value with an upper limit for the ionization potential of SF_3(IP≤9.25 eV, *5*), we obtain a lower limit for $D_0°$ (SF_3−F) of 78.9 kcal·mol^{-1}.

Two upper limit values for $D_0°$ (SF_3−F) can be obtained from threshold measurements by Harland and Thynne[6] on dissociative attachment in SF_6 and SF_4. We combine their AP(F^-/SF_4) = 0.20 ± 0.05 eV with the electron affinity of F(EA = 3.399 eV,)[1] to obtain $D_0°$ (SF_3−F) ≤ 83.0 kcal·mol^{-1}. In addition, their appearance potentials[6] for the formation of F^- from SF_6 by two distinct processes are combined directly to give $D_0°$ (SF_3−F) ≤ 80.7 kcal·mol^{-1}.

The AP of SF_3^+ from SF_6 has been measured by electron–impact[3,7] and photoelectron spectroscopy.[8] These three threshold values are in agreement with AP(SF_3^+/SF_6) = 19.97 ± 0.1 eV. Assuming the ionization process to be SF_6(g) + e^- = SF_3^+(g) + 3 F(g) + 2 e^-, we combine the mean AP value with IP(SF_3) ≤ 9.25 eV[5] to obtain $\Delta_f H°$(SF_3, g, 0 K) < − 96.3 kcal·mol^{-1}. This result conflicts with all of the other available information; thus, we are led to conclude that the formation of SF_3^+ from SF_6 probably involves significant kinetic and/or excitation energies.

Heat Capacity and Entropy

We assume a molecular structure in which the four atoms form a slightly distorted T–shaped molecule having bond angles similar to those for ClF_3.[1] We eliminate a nonplanar pyramid (C_{3v} symmetry) as a plausible structure since recent ESR studies[9] show that the radical has only two equivalent fluorine nuclei. The equatorial and axial S–F bond lengths are assumed to be equal to those for SF_4.[1] The principal moments of inertia are: I_A = 5.8076 × 10^{-39}, I_B = 17.0895 × 10^{-39}, and I_C = 22.8971 × 10^{-39} g·cm^2.

The vibrational representation for the adopted structure is $3A_1 + 2B_1 + B_2$. We estimate the six fundamentals according to symmetry species by analogy with the frequencies and assignments for ClF_3 and SF_4.[1,10] Since several of the assignments for SF_4[11] are uncertain, more weight is given to the results for ClF_3. Bott[2] detected IR radiation in emission at 11.0–12.6 μ in SF_4/Ar mixtures which were shock–heated to temperatures above 2050 K. He attributed this radiation to SF_3, indicating that at least one fundamental lies in the region 794–909 cm^{-1}. We assume that the unpaired electron will form all doublet states, and we include an excited level at 25000 cm^{-1} by analogy with that which has been observed for SF_4^+.[8]

Wilkins[12] has previously reported thermal functions for SF_3 which cover an extended temperature range (0–6000 K). These functions are based on a pyramidal structure and vibrational frequencies obtained from estimated force constants. Since this structure now appears to be incorrect, our functions are believed to be more reliable.

Enthalpy of Formation

Glemser *et al.*[1] determined AP(SF_3^+) = 12.70 ± 0.03 eV from electron–impact measurements on SF_4. Their results[1] are confirmed by the subsequent measurements of Hildenbrand[2] who reported AP values of 12.63 ± 0.1 eV (from SF_4) and 12.8 eV (from SF_4 formed as a reaction product in $SF_6 + C$). From these results we arrive at a $\Delta_f H°(0\ K) = 293.1 \pm 2.3$ kcal·mol^{-1} (mean AP value) for the process $SF_4(g) + e^- = SF_3^+(g) + F(g) + 2\,e^-$. Assuming that the products are formed with no excess energies, we combine the value of $\Delta_f H°(0\ K)$ with JANAF enthalpy of formation[3] for SF_4 and F to obtain the result, $\Delta_f H°(SF_3^+, g, 0\ K) = 93.84 \pm 8.0$ kcal·mol^{-1} which is adopted. Our $\Delta_f H°$ value corresponds to $IP(SF_3) = 213.1 \pm 16.0$ kcal·mol^{-1} (9.24 ± 0.7 eV). This value is consistent with the observations of Fehsenfeld[4] who found no charge transfer reaction between NO and SF_3^+, suggesting that $IP(SF_3) < 9.25$ eV. In addition, we predict that $IP(SF_3) << IP(SF_2)$ due to a stabilization of the positive charge in the even–electron SF_3^+ cation by resonance structures such as $F_2S{=}F^+$. JANAF data[3] gives $IP(SF_2)–IP(SF_3) = 1.05$ eV which compares favorably with the 1–2 eV lowerings[5] observed in other di– and tri–fluoride molecules and radicals.

Paulett and Lustig [6] reported appearance potentials for SF_3^+ and SF_4+ from SF_5NF_2. We combine their results to arrive at $\Delta_f H°(0\ K) = 2.31 \pm 4.6$ kcal·mol^{-1} for the process $SF_4^+(g) + NF_3(g) = SF_3^+(g) + NF_2(g) + F_2(g)$ which leads to $\Delta_f H°(SF_3^+, g, 0\ K) = 61.5$ kcal·mol^{-1}. This value is in poor agreement with the adopted result, suggesting that the fragmentation processes involving SF_5NF_2 probably include unknown excess energy terms. Other reported fragment–ion appearance potentials for SF^+ have been previously analyzed (refer to $SF_3(g)$ and $SF_4(g)$ tables) and were shown to be seriously in error.

$\Delta_f H°(298.15\ K)$ is calculated to be 94.07 kcal·mol^{-1}. Using JANAF data.[3] we find that the primary bond dissociation energy $D_0°(SF_2^+–F)$ is 91.4 kcal·mol^{-1} which when compared with $D_0°$ values for SF_3 (67.3 kcal·mol^{-1}) and SF_3^- (106.4 kcal·mol^{-1}) indicates that the trend is $D_0°(SF_3^-) > D_0°(SF_3^+) >> D_0°(SF_3)$. The observed increased bond strengths in both ions relative to the SF_3 radical provide additional support to the view that the positive and negative charges are delocalized in the even–electron ions. Furthermore, available structural information shows that the bond length in SF_3^+ is the shortest S–F bond that has so far been reported. The heat of atomization, $\Delta_{at} H°(0\ K)$, and average bond dissociation energy are 265.9 kcal·mol^{-1} and 88.6 kcal·mol^{-1}, respectively.

Heat Capacity and Entropy

The molecular structure and vibrational frequencies are those measured by Gibler *et al.*[7] for the SF_3^+ ion in the solid SF_4BF_3 adduct. We adopt average values of the bond lengths and angles reported by Gibler *et al.*[7] since spectroscopic evidence[8] indicates that in crystal adducts the SF_3^+ symmetry is lowered somewhat as a result of flourine bridging with the anion. The adopted bond length is estimated to be within ±2.0% of the true gas–phase value, based on a comparison of structural data for gaseous and crystalline ClF_3.[9] The adopted bond angle (97.51°) is close to the gas–phase value (97.8 ± 0.2°) found for the isoelectronic molecule PF_3,[3] suggesting that the gas–phase bond angle for SF_3^+ is probably within ±0.5° of the adopted solid–state value. Our frequencies show good agreement with those determined by Azeem *et al.*[8] in their infrared and Raman studies of solid adducts of SF_4 with several fluoride acceptors. Their results[8] indicate that the SF_3^+ frequencies are relatively independent of the anion and are not significantly different when measured in the liquid state. Thus, we believe that the error introduced in the SF_3^+ thermal functions by use of solid–state frequencies is probably small. The individual moments of inertia are: $I_A = 1.5987 \times 10^{-38}$, $I_B = 9.8733 \times 10^{-39}$, and $I_C = 9.8733 \times 10^{-39}$ g·cm^2.

Delwiche[10] has reported an ionization efficiency curve for SF_3^+ which was obtained by retarded potential difference (RPD) measurements. This curve reveals the existence of an excited state, lying 2177 cm^{-1} above the ground state. We include this level and assume that the ground and excited states are both singlets since SF_3^+ has no unpaired electrons.

Enthalpy of Formation

Using time–of–flight measurements, Harland and Thynne[1,2] have identified SF_3^- in the negative ion mass spectra of SF_4, SF_6, and SF_5Cl. Ionization efficiency curves obtained for a dissociative resonance capture process involving SF_4 were analyzed by a deconvolution procedure to give an appearance potential (AP) for SF_3^- of 0.70 ± 0.05 eV. Harland and Thynne[1] suggested that the process responsible for ion formation was $SF_4(g) + e^- = SF_3^-(g) + F(g)$. Assuming that the products are formed with no excess energies, we assign the measured value of AP to $\Delta_f H°$ of the proposed ion–formation process, and we obtain the adopted value, $\Delta_f H°(SF_3^-, g, 0\ K) = -183.1 \pm 7.0$ $kcal·mol^{-1}$ by combining $\Delta_f H°(0\ K)$ with JANAF enthalpies of formation[3] for SF_4 and F. Using this $\Delta_f H°$ value, we calculate $EA(SF_3) = 2.72 \pm 0.65$ eV and a fluoride–ion affinity (IA) of $IA(SF_2) = 52.7$ $kcal·mol^{-1}$. This value of EA is in excellent agreement with the result (EA = 2.71 eV) obtained by a magnetron technique,[4] suggesting that the electron–impact data are reliable and that the interpretation is correct.

The electron–impact AP for SF_3^- from SF_5Cl has been reported[2] as 7.0 ± 0.2 eV. Harland and Thynne[1,2] have suggested two ion formation processes; namely, (A) $SF_5Cl(g) + e^- = SF_3^-(g) + F(g) + FCl(g)$ and (B) $SF_5Cl(g) + e^- = SF_3^-(g) + 2\ F(g) + Cl(g)$. We eliminate (A) as a plausible process since it leads to $EA(SF_3) = -2.1$ eV. We are unable to reproduce the result (EA = 2.9 ± 0.1 eV) obtained for process (A) by Harland and Thynne[1] and believe their calculations to be in error. Process (B) leads to $EA(SF_3) = 0.5$ eV which suggests that $EA(SF_3) < EA(SF_4)$. We believe that this is very unlikely based on trends in the electron affinities for S–F species.[3] We conclude that process (B) very likely involves excess energy terms, amounting to about 2.2 eV.

$\Delta_f H°(298.15\ K)$ is calculated to be -185.6 $kcal·mol^{-1}$ at 298.15 K. In addition, we find that the primary bond dissociation energy $D_0°(SF_2-F)$ is 108.0 $kcal·mol^{-1}$ which when compared with JANAF $D_0°$ values for SF_3^+(91.4 $kcal·mol^{-1}$) and SF_3(67.3 $kcal·mol^{-1}$) indicates that the trend is $D_0°(SF_3^-) > D_0°(SF_3^+) >> D_0°(SF_3)$. The observed increased bond strengths in both ions relative to the SF_3 radical suggest that the positive and negative charges are delocalized in the even–electron ions. Further evidence supporting this view is presented on the SF_3^+ (g) table.[3] The enthalpy of atomization and average bond dissociation energy are 225.6 $kcal·mol^{-1}$ and 75.2 $kcal·mol^{-1}$, respectively.

Heat Capacity and Entropy

SF_3^- has 28 valence electrons, and according to the Walsh correlation diagram,[5] the ion should have a planar structure. We predict that this planar structure will have a slightly distorted T–shape (C_{2v} symmetry) by analogy with that for the isoelectronic molecule ClF_3.[3] As pointed out by Frey *et al.*,[6] the slightly distorted T–shaped structure of ClF_3 is closely related to the trigonal bipyramidal structure of SF_4. We estimate structural data for SF_3^- from that for SF_4[3] by considering the effects of removing one of its equatorial fluorine atoms. We assume that this removal process would produce no change in the S–F bond lengths and only minor changes in the bond angles. The structural data obtained in this way appear reasonable in comparison with that for ClF_3.[3] The individual moments of inertia are: $I_A = 5.5926 \times 10^{-39}$, $I_B = 17.0479 \times 10^{-39}$, and $I_C = 22.6406 \times 10^{-39}$ $g·cm^2$.

The vibrational representation for the adopted structure of SF_3^- is $3A_1 + 2B_1 + B_2$. We estimate the fundamentals according to symmetry species by analogy with the frequencies and assignments for ClF_3 and SF_4.[3,6] Since several of the assignments for SF_4[7] are uncertain, more weight is given to the results for ClF_3. We assume a singlet ground state (no unpaired electrons) and neglect excited states.

Enthalpy of Formation

$\Delta_f H°(SiF_3, g, 298.15\ K) = -259.4 \pm 2\ kcal \cdot mol^{-1}$ is derived from the mass spectrometric equilibrium constants determined by Farber[9] for the reaction $SiF_4(g) + SiF_2(g) = 2SiF_3(g)$. Our 2nd and 3rd law analysis of the ten points in the 1590 to 1782 K range, using auxiliary data,[1] gives $\Delta_r H°(298.15\ K) = 7.47 \pm 0.19\ kcal \cdot mol^{-1}$ (2nd law) and $\Delta_r H°(298.15\ K) = 7.61 \pm 0.04\ kcal \cdot mol^{-1}$ (3rd law) with a drift of 0.09 ± 0.11 cal $K^{-1} \cdot mol^{-1}$ (3rd law). The 3rd law heat of reaction leads to the adopted enthalpy of formation. The adopted value is consistent with the total pressure data above the silicon–magnesium fluoride system observed by Layne.[2] The value of $\Delta_f H° = -235 \pm 20\ kcal \cdot mol^{-1}$, derived by McDonald *et al.*[3] from appearance and ionization potentials and by Wang *et al.*[4] from appearance potentials and translational energies, appears to be too positive. A later paper by Franklin[10] suggests that the assumption of the fraction of active vibrations as a constant may have caused a bias of 15 $kcal \cdot mol^{-1}$ or more in the derived enthalpy of formation.

$\Delta_f H°(0\ K) = -258.7\ kcal \cdot mol^{-1}$ corresponds to $\Delta_a H°(0\ K) = 420.4\ kcal \cdot mol^{-1}$, using auxiliary data.[1] The average bond energies in $SiF_2(g)$, $SiF_3(g)$, and $SiF_4(g)$ are all within ~2 $kcal \cdot mol^{-1}$.

Heat Capacity and Entropy

The electronic levels are those tentatively assigned by Wang *et al.*[5] from emission spectral observations. The first excited state is designated as ^2E, rather than ^2B, as stated by So[11] based on ab initio Hartree–Fock calculations and group theory arguments. The vibrational frequencies are derived from matrix–isolation UV and IR spectra of Milligan *et al.*[6] They also determined the angle between the Si–F bonds and the three–fold axis to be $71 \pm 2°$ which is consistent with the adopted tetrahedral F–Si–F bond angle. Theoretical calculations[7,8,11] indicate that this angle should be somewhat less than the tetrahedral angle. Calculations based on a bond angle of 108° decrease $S°(298.15\ K)$ by 0.029 cal $K^{-1} \cdot mol^{-1}$. As suggested by Milligan *et al.*,[6] the Si–F bond length is assumed to be that in $SiHF_3$.[1] The C_{3v} structure is well established by ESR studies.[12,13] The principal moments of inertia are $I_A = I_B = 11.1156 \times 10^{-39}$ and $I_C = 20.5365 \times 10^{-39}\ g \cdot cm^2$.

$\Delta_f H°$(0 K) = Unknown

$S°$(298.15 K) = [87.864 ± 12.6] J·K^{-1}·mol^{-1} $\Delta_f H°$(298.15 K) = −1435.530 ± 41.8 kJ·mol^{-1}

Enthalpy of Formation

Blocher and Hall[1] have reported vapor pressure data for the process 1/2 Hg_2F_2 + TiF_3(cr) = TiF_4(g) + Hg(l). 2nd and 3rd law analyses of their data give a 2nd law $\Delta_r H°$(298.15 K) of 23.7 kcal·mol^{-1}, a 3rd law $\Delta_r H°$(298.15 K) of 29.864, and a 3rd law drift of 11.9 ± 1.0 cal K^{-1}·mol^{-1}. The 3rd law value is combined with the JANAF values for the enthalpy of formation of Hg_2F_2(cr) and TiF_4(g) to give a $\Delta_f H°$(298.15 K) of −343.1 ± 10.0 kcal·mol^{-1}. The large uncertainty on $\Delta_f H°$(298.15 K) is assigned because Blocher and Hall were not able to identify TiF_3(cr) as the reaction product in the above process. They reported that the X-ray pattern of the products contained lines corresponding to Hg_2F_2(cr) plus others that did not correspond to TiF_3(cr).

Heat Capacity and Entropy

The heat capacity of TiF_3(cr) is estimated from the heat capacities of ZrF_4 and TiF_4. The entropy, $S°$(298.15 K), is estimated from CrF_3 and from ionic entropy contributions. Both methods give values which are within ±0.5 cal K^{-1}·mol^{-1} of the chosen value of 21 ± 3 cal K^{-1}·mol^{-1}.

Sublimation Data

The heat of sublimation is calculated from the vapor pressure data of Zmbov and Margrave.[2] Refer to TiF_3(g) table for details. The sublimation temperature is taken as temperature at which the fugacity is one atmosphere for the process TiF_3(cr) = TiF_3(g).

Enthalpy of Formation

The enthalpy of formation of $TiF_3(g)$ is calculated from that of $TiF_3(cr)$ and the enthalpy of sublimation determined from the mass spectrometric vapor pressure data of Zmbov and Margrave.[1] Their data give nine points over the temperature range 759–865 K.

2nd and 3rd law analyses of their data give a 2nd law $\Delta_{sub}H°(298.15\ K)$ of 61.2 ± 0.4 kcal·mol^{-1} and a 3rd law $\Delta_{sub}H°(298.15\ K)$ of 59.0 kcal·mol^{-1} with an entropy drift of −2.7 ± 0.5 units. The 3rd law value is used to calculate $\Delta_f H°(298.15\ K)$.

Heat Capacity and Entropy

The interatomic distance is estimated from those of $TiF_4(g)$, and $TiCl_4(g)$, and $TiCl_3(g)$. The pyramidal bond angle is estimated assuming $TiF_3(g)$ similar to the group V trihalides. The principal moments of inertia are $I_A = I_B = 16.7602 \times 10^{-39}$ and $I_C = 26.7330 \times 10^{-39}\ g \cdot cm^2$. The vibrational frequencies are estimated from those of PF_3 and AsF_3. The electronic levels are estimated from the levels of Ti^{+3}.[2]

$S°(298.15\ K) = [87.864 \pm 8.4]\ J \cdot K^{-1} \cdot mol^{-1}$

$\Delta_f H°(0\ K)$ = Unknown

$\Delta_f H°(298.15\ K) = [-1401.640 \pm 83.7]\ kJ \cdot mol^{-1}$

Enthalpy of Formation

The enthalpy of formation at 298.15 K for ZrF_3(cr) was reported as $-350\ kcal \cdot mol^{-1}$ [1] which was estimated by Brewer.[2] Based on this $\Delta_f H°(298.15\ K)$ value, the crystal lattice energy (U) of ZrF_3(cr) is calculated to be 1371 $kcal \cdot mol^{-1}$ by the Born–Haber cycle method.[3] For the evaluation of U from the relation: $\Delta_f H°(ZrF_3, cr, 298.15\ K) = \Sigma I_i + L - 3(E - D/2) - U$, the following values ($kcal \cdot mol^{-1}$) are used: ΣI_i (the sum of the successive three ionization potentials of Zr metal) = 1055[4] L (the enthalpy of sublimation of Zr metal) = 148.3[5] E (the electron affinity of fluorine) = 79.5[6] and D (the enthalpy of dissociation of fluorine) = 37.7).[5] The derived value of $U(ZrF_3, cr)$ is of the same order of magnitude of the value, $U(TiF_3, cr)$ = 1376 $kcal \cdot mol^{-1}$, calculated by Cavell and Clark[3] using the same method.

From $\Delta_f H°(ZrF_3, cr, 298.15\ K) = -350\ kcal \cdot mol^{-1}$, the derived $\Delta_f G(ZrF_3, cr)$ values indicate that ZrF_3(cr) is thermodynamically more stable than the system ZrF_4(cr) + Zr(cr). For example, in the temperature range 298–1200 K, the Gibbs energy changes for the reaction 3 ZrF_4(cr) + Zr(cr) = 4 ZrF_3(cr) are about $-29 \pm 1\ kcal \cdot mol^{-1}$. However, this product ZrF_3(cr) has never been prepared successfully from this reaction in many laboratories.[7] In order to make the $\Delta_f G°(ZrF_3, cr, 298.15\ K)$ values consistent with the experimental observations, the enthalpy of formation of ZrF_3(cr) is arbitrarily adjusted to be 15 $kcal \cdot mol^{-1}$ less negative, or $\Delta_f H°(ZrF_3, cr, 298.15\ K) = -335\ kcal \cdot mol^{-1}$ with uncertainty as high as $\pm 20\ kcal \cdot mol^{-1}$. This value is tentatively adopted.

The Gibbs energy changes for the reaction 3 $ZrF_4(g)$ + Zr(cr) = 4 ZrF_3(cr) are evaluated to be very favorable at temperatures below 900 K, e.g., $\Delta_r G° = -93.9$ and $-6.7\ kcal \cdot mol^{-1}$ at 298 and 900 K, respectively. But according to Larsen and Leddy[8] this reaction does not occur in the temperature range 473–973 K, and pressure range 5–15 atm. One possible explanation is that these heterogeneous reactants may require very high activation energy to initiate the reaction. In other words, this reaction is unfavorable at these temperatures probably due to kinetic rather than thermodynamic reasons.

Heat Capacity and Entropy

The heat capacities of ZrF_3(cr) are not available in the literature. They are estimated from the $C_p°$ values of ZrF_4(cr) by deduction of one F atom $C_p°$ contributions which are calculated as $1/4[C_p°(ZrF_4, cr) - C_p°(Zr, cr)]$. The $S°(298.15\ K)$ is taken to be $1/2[S°(ZrF_4, cr, 298.15\ K) + S°(ZrF_2, cr, 298.15\ K)]$ of which the value $S°(ZrF_2, cr, 298.15\ K)$ is estimated; refer to ZrF_2(cr) table for details.

Sublimation Data

The difference between $\Delta_f H°(298.15\ K)$ for $ZrF_3(g)$ and ZrF_3(cr) is $\Delta_{sub} H°(298.15\ K)$. Actually ZrF_3(cr) is thermodynamically unstable, e.g., the Gibbs energy changes for the reaction 4 ZrF_3(cr) = 3 ZrF_4(cr) + Zr(cr) are about $-30\ kcal \cdot mol^{-1}$ in the temperature range 298–1400 K. In other words, ZrF_3(cr) decomposes into ZrF_4(cr) + Zr(cr) before sublimation occurs.

Enthalpy of Formation

Murad and Hildenbrand[1] studied the gaseous equilibria involving ZrF_4, ZrF_3, ZrF_2, Ca and CaF. These species were generated at high temperatures in a graphite Knudsen cell containing powdered calcium fluoride and elemental zirconium. Ion intensities were measured 3 eV above threshold over the temperature range 1665–1747 K and the equilibrium constants were calculated for the following isomolecular reaction: $Ca(g) + ZrF_4(g) = CaF(g) + ZrF_3(g)$. Based on the reported equilibrum constants the enthalpy change of this reaction is evaluated by the 2nd and 3rd law methods to be -8.0 ± 25 and 28.0 ± 2 kcal·mol^{-1}, respectively. The 3rd law entropy drift is 20 ± 15 cal K^{-1}·mol^{-1}. Using the 3rd law value and $\Delta_f H°(298.15\ K) = 42.85 \pm 0.3$, -400.0 ± 0.5, and -65.0 ± 2 kcal·mol^{-1} for Ca(g), ZrF_4(g), and CaF(g) we obtain $\Delta_f H°(ZrF_3, g, 298.15\ K) = -264.2 \pm 5$ kcal·mol^{-1} which is adopted. Employing slightly different Gibbs energy functions and $\Delta_f H°(298.15\ K)$ values for the products and reactants, Murad and Hildenbrand[1] evaluated the 3rd law enthalpy change of the above reaction as 29.4 ± 5 and $\Delta_f H°(ZrF_3, g, 298.15\ K) = -262 \pm 5$ kcal·mol^{-1} which are in reasonable agreement with the values adopted here.

Heat Capacity and Entropy

The molecular structure is assumed to be the same as that of TiF_3(g). The Zr–F bond distance is estimated by comparison with those for ZrF_4(g) and ZrF_2(g). The F–Zr–F bond angle is taken to be slightly bigger than the F–Ti–F bond angle in TiF_3(g) molecule. The vibrational frequencies are calculated by the valence force method[2] using force constants transferred from those for the ZrF_2(g) molecule. The three principal moments of inertia are: $I_A = I_B = 18.2815 \times 10^{-39}$ and $I_C = 29.5856 \times 10^{-39}$ g·cm^2. The electronic levels are estimated to be three times higher than those of TiF_3(g), based on the ratio of the first splitting interval between Ti(IV) and Zr(IV), given by Moore.[3] The quantum weights are assumed to be the same as those of TiF_3(g).

Ground State Quantum Weight: 1 σ = [4]
Point Group: C_4
Bond Distance: F–F = [2.5] Å
Product of the Moments of Inertia: $I_A I_B I_C = [1.790364 \times 10^{-113}]\ g^3·cm^6$

Enthalpy of Formation

The enthalpy of 4 HF(g) → H_4F_4(g) was taken as the mean of 3rd law values which were determined from the equilibrium data of two investigations. Briegleb and Strohmeier[1] measured the vapor density of associated HF between 20 and 60°C and between 50 and 650 torr. Franck and Meyer[2] measured $C_p^°$ between −20 and 100 °C and between 100 and 700 torr. Each investigation evaluated K_p at n = 2, 3,4, ... for the reactions n(HF) → $(HF)_n$ and reported 2nd law values of $\Delta H°$ and $\Delta S°$. At n = 4 their 2nd law values differed by 4.2 $kcal·mol^{-1}$, which was taken as an estimate of error, while the calculated 3rd law values differed by 1.5 $kcal·mol^{-1}$. Using $\Delta_f H°(298.15\ K) = -22.38\ kcal·mol^{-1}$ and auxiliary JANAF data[3] gives the enthalpy of formation of H_4F_4(g).

Heat Capacity and Entropy

The molecular structure of H_4F_4 was assumed as planar with the F atoms forming the vertices of a square and with the H atoms also lying in the circumscribed circle. That rings are more stable than open chains was confirmed by Del Bene and Pople's[4] theoretical molecular-orbital studies on HF polymers. The length of side (F–F axis) was taken from Atoji and Lipscomb's[5] X-ray studies of solid HF (F–F = 2.49 Å) and agrees with the 2.52Å which Janzen and Bartell[6] determined for the gaseous polymers by electron diffraction. The low F–bending frequency (53 cm^{-1}) was taken from Boutin *et al.*[7] The other vibrational frequencies were taken from Kittelberger and Hornig's[8] work on crystalline HF. Huong and Couzi[9] and Smith[10] have made spectral studies of the gas phase in the range from 350 to 4000 cm^{-1}.

National Bureau of Standards prepared this table[11] by critical analysis of data existing in 1972. Using molecular constants and $\Delta_f H°$ selected by NBS,[11] we recalculate the table in terms of 1973 fundamental constants,[12] 1975 atomic weights,[13] and current JANAF reference states for the elements.

Ground State Quantum Weight: [1] $\sigma = 4$

Point Group: $[D_{2h}]$

Bond Distances: Mg–F = [1.77] Å; Mg–F' = [1.96] Å

Bond Angles: Mg–F'–Mg = [90]°; F'–Mg–F' = [90]°; F–Mg–F' = [135]°

(F' = Ring Fluorine)

Product of Moments of Inertia: $I_A I_B I_C = [8.5873 \times 10^{-113}]\ g^3 \cdot cm^6$

Enthalpy of Formation

Berkowitz and Marquart[1] have found approximately 1% dimer in the equilibrium vapor over MgF_2(cr) at about 1400 K by mass spectrometry. Independent measurements which are discussed elsewhere (See MgF_2(g) table) support their results. Berkowitz and Marquart[1] reported a 2nd law $\Delta_f H°$(1440 K) of 30 kcal·mol^{-1} for the reaction MgF_2(cr) + MgF_2(g) = Mg_2F_2(g). This value corrected to 298.15 K gives $\Delta_f H° = 31.7$ kcal·mol^{-1} which leads to $\Delta_f H°(Mg_2F_4, g, 298.15\ K) = -410.7$ kcal·mol^{-1}. The corresponding heat of dimerization at 298.15 K is −63.3 kcal·mol^{-1}. Berkowitz and Marquart[1] also reported approximate absolute pressures for MgF_2(g) and Mg_2F_4(g) at 1429 K. A 3rd law analysis of these reported pressures gives $\Delta_r H°(298.15\ K)$ of −69.5 kcal·mol^{-1} for the process $2MgF_2(g) = Mg_2F_4(g)$, or $\Delta_f H°(Mg_2F_4, g, 298.15\ K) = -416.9$ kcal·mol^{-1}. We prefer the 2nd law result $\Delta_f H° = 410.7$ kcal·mol^{-1} since the else negative (−63.3 kcal·mol^{-1}) heat of dimerization is more consistent with the dimerization energies for the alkali metal fluorides.[2] The uncertainty in $\Delta_f H°$ is estimated as ±5.0 kcal·mol^{-1}, however, we also include an alternate uncertainty (±9 kcal·mol^{-1}) to cover the possibility that M_gF_2(g) is linear.[2]

Heat Capacity and Entropy

The dimer is assumed to have a bridge–bond structure of D_{2h} symmetry similar to that suggested by Thompson and Carlson[3] for the dimers of several transition metal dichlorides. The two outer Mg–F bond lengths are assumed to be the same as that for MgF_2.[2] The four ring Mg–F' bond lengths are assumed to be 10% longer. The four atoms which lie in the ring form a square. The F'–MgF' bond angle is estimated as 135°. The individual moments of inertia are: $I_A = 9.0458 \times 10^{-38}$, $I_B = 7.8340 \times 10^{-38}$ and $I_C = 1.2118 \times 10^{-38}$ g·cm^2.

This planar bridge–bond structure will have six Raman ($3A_g + 2B_{1g} + 2B_{2g}$) and six infrared ($2B_{1u} + 2B_{2u} + 2B_{3u}$) active fundamentals. The Raman spectra of MgF_2 isolated in an argon matrix has been recorded by Lesiecki and Nibler.[4] They assigned two bands observed at 585 and 353 cm^{-1} to ν_1 and ν_2, respectively, of Mg_2F_4. Lesiecki and Nibler,[4] using a standard high–low frequency separation method and a diagonal force field, calculated ν_4 as 508 cm^{-1}. The other three Raman active frequencies (ν_3, ν_5, ν_6) are estimated by analogy with those for MgF_2 and Na_2F_2.[2] Four of the six infrared active fundamentals have been osbserved and assigned by Lesiecki and Nibler.[4] These frequencies were recorded in an argon matrix. Results of three independent infrared studies.[5–7] conducted with various matrices support these assignments. The other two infrared active fundamentals (ν_8 and ν_{10}) are estimated from the bending frequency ($\nu_2 = 215$ cm^{-1}) for MgF_2.[2] Following the observations made by Thompson and Carlson,[3] all the estimated frequencies are taken to lie above the bending frequency of the monomer.

Point Group: [T_d] σ = [12]
Bond Distance: Mo–F = [1.82] Å
Bond Angle: F–Mo–F = [109.47]°
Product of the Moments of Inertia: $I_A I_B I_C$ = [2.163977 × 10^{-113}] g^3·cm^6

Enthalpy of Formation

We adopt the weighted average value derived by Brewer[1] from several divergent equilibria measurements. Weaver *et al.*[2] reported a partial pressure of 4.6 × 10^{-6} atm MoF_4(g) in equilibrium with Mo and MoF_3 solids at 973 K. Hildenbrand[3] has measured several gaseous equilibria for reactions involving MoF_4(g) [1143–2146 K]; and Alikhanyan[4] has measured partial pressures for the reaction $MoF_5(g) + MoF_3(g) = 2\ MoF_4(g)$ [911 and 964 K]. Our 3rd law analyses of the equilibrium reactions, using auxiliary data from Brewer[1] for the MoF_x compounds other than MoF_4(g) and other auxiliary data from the JANAF Thermochemical Tables,[5] leads to $\Delta_f H°(MoF_4, g, 298.15\ K)$ values ranging from −216.0 to −226.6 kcal·mol^{-1}. The value of $\Delta_f H°(0\ K)$ combined with JANAF data[5] for Mo(g) and F(g) gives $\Delta_{at} H°(0\ K)$ = 456.357 kcal·mol^{-1} and an average Mo–F bond energy of $\Delta_{at} H°(0\ K)/4$ = 114.1 ± 2 kcal·mol^{-1}.

Heat Capacity and Entropy

We use the vibrational frequencies and degeneracies estimated by Hildenbrand[3] and adopted by Brewer.[1] These are in reasonable agreement with the estimates of Tumanov and Galkin.[6] The structure is assumed to be tetrahedral and a Mo–F distance of 1.82 Å from MoF_6(g) is used. The electronic contributions are those estimated by Brewer[1] based on crystal field theory. The principal moments of inertia are: $I_A = I_B = I_C = 27.8666 \times 10^{39}$ g·cm^2.

This table is based on the critical analysis of data existing in 1978 by Brewer.[1]

Enthalpy of Formation

Zmbov *et al.*[1] investigated the stabilities of some molybdenum and tungsten oxyfluorides by means of mass spectrometry. These studies led to enthalpies of formation for MoO_2F_2(g), WO_2F_2(g), and WOF_4(g) which were used by the authors to develop a correlation among the enthalpies of formation of the oxides, oxyfluorides, and fluorides of Mo and W. $\Delta_f H°(298.15\ K)$ varies almost linearly with the number of oxygen atoms[1] for the series WF_6, WOF_4 and WO_2F_2. Assuming a similar variation for MoF_6, $MoOF_4$ and MoO_2F_2, we estimate $\Delta_f H°(MoOF_4, g) = -320\ kcal \cdot mol^{-1}$.

$\Delta_f H$ data[2] for MoF_6(g), MoO(g), MoO_2(g), and MoO_3(g) have been used to derive the following average bond dissociation energies:

$$\Delta H°(MoF, g)/6 = 107\ kcal \cdot mol^{-1}$$
$$\Delta H°(MoO_n, g)/n = 135\ kcal \cdot mol^{-1}$$

From these data we derive $\Delta_f H°(MoOF_4, g) = -271\ kcal \cdot mol^{-1}$.

The enthalpy of formation for $MoOF_4$ is tentatively selected as $-300 \pm 30\ kcal \cdot mol^{-1}$.

Heat Capacity and Entropy

Blanchard[3] suggested that $MoOF_4$(g) possessed C_{4v} symmetry by reason of the similarity of its infrared spectra with that of $XeOF_4$(g). X-ray diffraction studies of crystalline $MoOF_4$ by Edwards *et al.*[4,5] support this view. The structure of the molecule is assumed to be square-pyramidal. The bond lengths are from the crystallographic studies of $MoOF_4$ by Edwards *et al.*[4,5] Individual moments of inertia are $I_A = I_B = 27.437 \times 10^{-39}$, $I_C = 41.8010 \times 10^{-39}\ g \cdot cm^2$.

Blanchard[3] reported the following vibrational frequencies and assignments:

$$\nu_1 = 1045,\ \nu_7 = 720,\ \nu_3 = 680,\ \text{and}\ \nu_8 = 530\ cm^{-1}.$$

Similar frequencies have been reported by Edwards *et al.*[4] from their study of the infrared spectra of gaseous $MoOF_4$. The rest of the frequencies and assignments are estimated by comparison with data for $XeOF_4$.[6]

Ground State Quantum Weight: 1 $\sigma = 2$
Point Group: C_2
Bond Distances: N–N = [1.47] Å; N–F = [1.37] Å
Bond Angles: F–N–F = [108]°; N–N–F = [104]°; Dihedral Angle = [65]°
Product of the Moments of Inertia: $I_A I_B I_C = [1.1817 \times 10^{-113}]\ g^3·cm^6$

Enthalpy of Formation

Armstrong *et al.*[1] studied the reaction $N_2F_4(g) + 16/3\ NH_3(g) = 4\ NH_4F(s) + 5/3\ N_2(g)$. From this reaction, they calculate the enthalpy of formation of N_2F_4 to be $-2.0 \pm 2.5\ kcal·mol^{-1}$. The recalculated enthalpy of formation of $NH_4F(s)$ (refer to NF_2 table) differs from the value quoted in Circular 500 by 0.06 $kcal·mol^{-1}$. This correction would make the enthalpy of formation of tetrafluorohydrazine more negative by 0.24 $kcal·mol^{-1}$. In view of the large uncertainty in the enthalpy of formation, however, this correction was not applied.

Heat Capacity and Entropy – N_2F_4(g)

The fundamental frequencies were taken from the vapor phase infrared work of Durig and Lord.[2] The principal moments of inertia were calculated from the rotational constants reported by Lide and Mann.[3] Lide and Mann calculated the bond angles for assumed values of the NN and NF distance.

The principal moments of inertia are: $I_A = 1.5051 \times 10^{-38}$, $I_B = 2.6315 \times 10^{-38}$, and $I_C = 2.9836 \times 10^{-38}\ g·cm^2$.

Heat Capacity and Entropy – NF_2(g)

Harmony *et al.*[4] investigated the infrared spectrum of NF_2. They were able to assign the band center at 1074 cm^{-1} to the symmetric stretching mode ν_1. The absorption in the 930–940 cm^{-1} region was assigned to ν_3.

Harmony and Myers [5] performed matrix isolation experiments on NF_2. They arrived at the assignment $\nu_1 = 1070\ cm^{-1}$, $\nu_2 = 573\ cm^{-1}$ and $\nu_3 = 931\ cm^{-1}$. The stretching frequencies for similar molecules in an N_2 matrix are about 5 cm^{-1} below the gas phase values. A comparison of the gas phase and matrix values of ν_1 show excellent agreement.

Johnson and Colburn[6] report infrared studies on NF_2 but they draw no definite conclusions.

The gas phase value for ν_1 and the matrix values of ν_2 and ν_3 were taken to represent the fundamental vibrational frequencies of NF_2.

Harmony *et al.*[4] estimated the N–F distance as 1.37 and used this with their data to calculate an F–N–F angle of 104.2°. Using these data the moments of inertia are: $I_A = 7.3728 \times 10^{-39}$, $I_B = 1.2035 \times 10^{-39}$, and $I_C = 8.5763 \times 10^{-39}\ g·cm^2$.

Tungsten Fluoride Oxide (WF_4O) CRYSTAL M_r = 275.843012

$S°(298.15\ K) = 175.728 \pm 4.2\ J \cdot K^{-1} \cdot mol^{-1}$
$T_{fus} = 379\ K$

$\Delta_f H°(0\ K)$ = Unknown
$\Delta_f H°(298.15\ K) = -1406.908 \pm 62.8\ kJ \cdot mol^{-1}$
$\Delta_{fus} H° = 5.021 \pm 4.2\ kJ \cdot mol^{-1}$

Enthalpy of Formation

The enthalpy of formation, $\Delta_f H°(WOF_4, cr, 298.15\ K) = -333.26\ kcal \cdot mol^{-1}$, is calculated from the enthalpy of formation of $WOF_4(g)$ less the enthalpy of sublimation, $\Delta_{sub} H°(298.15\ K) = 16.80\ kcal \cdot mol^{-1}$. This latter quantity is calculated by the 3rd law method from the vapor pressure equation determined by Cady and Hargreaves.[1] The 2nd law value is $\Delta_{sub} H°(298.15\ K) = 16.94\ kcal \cdot mol^{-1}$.

Heat Capacity and Entropy

The heat capacities are estimated from those of $WOCl_4(cr)$, $WO_3(cr)$, $WO_2(cr)$, $WCl_6(cr)$, and $WF_6(cr, l)$.[3]

The entropy, $S°(298.15\ K) = 42.0\ cal\ K^{-1} \cdot mol^{-1}$ is calculated from the vapor pressure equaiton of Cady and Hargreaves[1] using a 2nd law analysis.

This entropy is larger than the corresponding value for $WOCl_4(cr)$.[2] In both cases the entropies of the condensed phases are derived from gas phase values using 2nd law analysis of sublimation and vaporization data. The entropy of melting for $WOCl_4$ is an order of magnitude larger than that of WOF_4. This suggests some inconsistency in the data for $WOCl_4$ since all values for $WOF_4(cr, l, g)$ appear internally reasonable.

Fusion Data

T_{fus} is calculated as the temperature at which the Gibbs energy of reaction $WOF_4(cr) \rightarrow WOF_4(l)$ approaches zero. The difference between the enthalpies of formation for the crystal and liquid at the melting point is $\Delta_{fus} H°$.

Ruff *et al.*[3] reported the melting point as 383 K. Cady and Hargreaves[1] calculated the melting point as 378 K, and the heat of fusion as $2.26\ kcal \cdot mol^{-1}$ from vapor pressure equations for the crystal and liquid. This 2nd law value of $\Delta_{fus} H°$, when corrected for $\Delta C_p°$ of vaporization and sublimation, is in good agreement with the value adopted in this table.

PREVIOUS: March 1967 CURRENT: December 1971

$S°(298.15\ K) = 178.915 \pm 4.2\ J \cdot K^{-1} \cdot mol^{-1}$
$T_{fus} = 379\ K$

$\Delta_f H°(298.15\ K) = -1405.255 \pm 62.8\ kJ \cdot mol^{-1}$
$\Delta_{fus} H° = 5.021 \pm 4.2\ kJ \cdot mol^{-1}$

Enthalpy of Formation

The enthalpy of formation, $\Delta_f H°(WOF_4, l, 298.15\ K) = -335.84\ kcal \cdot mol^{-1}$ is calculated from that of the gas less the enthalpy eat of vaporization, $\Delta_{vap} H°(298.15\ K) = 16.38\ kcal \cdot mol^{-1}$. This latter value is calculated by the 3rd law method from the vapor pressure equation determined by Cady and Hargreaves.[1] The 2nd law value is $\Delta_{vap} H°(298.15\ K) = 16.50\ kcal \cdot mol^{-1}$.

Heat Capacity and Entropy

The heat capacity is assumed to be constant at 7.25 cal K^{-1} g-atom^{-1} as suggested by Kubaschewski and Evans.[2] The entropy, $S°(298.15\ K) = 42.8\ cal\ K^{-1} \cdot mol^{-1}$ is calculated by a 2nd law analysis of the vapor pressure equation given by Cady and Hargreaves[1] for the system $WOF_4(l) \rightarrow WOF_4(g)$.

Fusion Data

Refer to the crystal table for details.

Vaporization Data

T_{vap} is calculated as the temperature at which the fugacity is one atmosphere for the process $WOF_4(l) \rightarrow WOF_4(g)$. The difference between the enthalpies of formation for the liquid and gas at T_{vap} is $\Delta_{vap} H°$.

Ruff *et al.*[3] reported the boiling point of WOF_4(l) as 459 K. Cady and Hargreaves[1] calculated the boiling point as 459 K, and the enthalpy eat of vaporization as 14.23 $kcal \cdot mol^{-1}$ from the vapor pressure equation for the liquid. This 2nd law value of $\Delta_{vap} H°$, when corrected for $\Delta C_p°$ of vaporization, is in good agreement with the value adopted in the tabulation.

Enthalpy of Formation

The enthalpy of formation, $\Delta_f H°(WOF_4, g, 298.15\ K) = -319.46\ kcal·mol^{-1}$, is calculated from the enthalpy of reaction data of Zmbov *et al.*[1] This data came from a mass spectrometric study of the equilibrium in the reaction:

$$2\ TaF_5(g) + WO_3(cr) = 2\ TaOF_3(g) + WOF_4(g).$$

Heat Capacity and Entropy

The infrared spectra of WOF_4 and $MoOF_4$ in the vapor state are very similar[2, 3, 4] and have been interpreted on the basis of a monomeric unit with C_{4v} symmetry[5] by comparison with the spectrum of $XeOF_4$.[6] Thus, as with $XeOF_4$ and $MoOF_4$, gaseous WOF_4 is assumed to be C_{4v} symmetry with a square–pyamidal structure.

Blanchard[5] and Reynes[10] reported the following vibrational assignments and frequencies, the Q frequency being adopted in this tabulation:

ν_1 = 1064(R), 1055(Q), 1047(P); ν_7 = 705(R), 700(Q), 690(P); ν_3 = 745(R), 735(Q), 720(P); ν_8 = 560 cm^{-1}

Similar frequencies, as well as additional frequencies, have been reported by Ward and Stafford,[4] Edwards *et al.*,[3] and Edwards and Jones.[2] The remaining frequencies and assignments are estimated with regard to the preceding references, the data for X_3OF_4,[6] and results for $MoOF_4$.[7] There exists some controversy as the crystallographic structure of WOF_4. Beattie *et al.*[8] suggest fluorine–bridged tetramers as in $MoOF_4$[9] rather than an oxygen–bridged structure as suggested by Edwards and Jones.[2] This leads to significantly different bond lengths for W–F and W–O. Due to the similarities in the melt, solid, and vapor phase infrared spectra of $MoOF_4$ and WOF_4, one would suspect similar structures.[4, 8] The assumption is made that the structures are similar and thus the bond lengths are taken to be the same as those of $MoOF_4$. Further support for the bond length assumption is the similarity of bond lengths in MoO_3 and WO_3 and in MoF_6 and WF_6.[7]

Ground State Quantum Weight: [1] σ = [12]
Point Group: [T_d]
Bond Distance: Pb–F = [2.08] Å
Bond Angle: F–Pb–F = [109° 28']
Product of the Moments of Inertia: $I_A I_B I_C = [4.821770 \times 10^{-113}]\ g^3 \cdot cm^6$

Enthalpy of Formation

A 3rd law analysis of the partial pressure data at 988 K reported by Zmbov *et al.*[1] for the equilibrium 2 $PbF_2(g) = PbF_4(g) + Pb(g)$ gives $\Delta_f H°(298.15\ K) = -16.15\ kcal \cdot mol^{-1}$. There are inconsistencies in the published results but the partial pressure data are correctly given.[2] The 2nd law enthalpy of reaction derived by Zmbov *et al.*[1] from a graphical plot of six ion current quotient values vs. reciprocal temperature (approximately 1020 to 1110 K), when corrected to 298.15 K, is in agreement with the 3rd law value of $-16.15\ kcal \cdot mol^{-1}$. Combining this enthalpy of reaction with $\Delta_f H°(PbF_2, g, 298.15\ K) = -104.0 \pm 1\ kcal \cdot mol^{-1}$ [3] and $\Delta_f H°(Pb, g, 298.15\ K) = 46.75 \pm 0.13\ kcal \cdot mol^{-1}$ [3] gives the adopted $\Delta_f H°(PbF_4, g, 298.15\ K) = -270.9 \pm 5\ kcal \cdot mol^{-1}$. The adopted enthalpy of formation leads to a dissociation energy $\Delta_{at} H° = 16.96$ eV for the process $PbF_4(g) = Pb(g) + 4\,F(g)$. This is consistent with $\Delta_{at} H° = 8.10$ eV for $PbF_2(g)$ [3] and $D_0° = 3.64$ eV for PbF(g).[3]

Heat Capacity and Entropy

The molecular constants and vibrational frequencies are those calculated by Aleksandrovskaya *et al.*[4] Later works[5,6,7] mistakenly cite this work as observed data. A band at 663 cm^{-1} was recently observed in an infrared study by Hauge *et al.*[8] and was assigned to matrix isolated PbF_4. Calculation with infrared active $\nu_3 = 663\ cm^{-1}$ decreases $S°(298.15\ K)$ by 0.45 cal $K^{-1} \cdot mol^{-1}$. Only the calculated frequencies are used for the present table pending more complete observation.

Enthalpy of Formation

Data on $\Delta_f H°$ published prior to 1970 have been reviewed by O'Hare *et al.*[1] We reanalyze this earlier work together with more recent studies. Unless otherwise indicated, all auxiliary data are taken from JANAF tables.[2] We also include, for those reactions involving the formation of HF, $\Delta_f H°$ values which have been derived in previous analyses.[11, 12, 13]

Source	Method	Reaction	$\Delta_f H°(T/K)$ kcal·mol^{-1}	$\Delta_f H°(SF_4, g, 298.15\ K)$, From (Ref.)	kcal·mol^{-1} This Work
3	Calorimetric	$SF_4(g) + 2\ H_2(g) = 4\ HF(l) + S(cr)$	104.8(298)[b] ± 4.0	185.2[11, 12] 188.5[13]	184.7[a] ± 6.0
4	Calorimetric	$SF_4(g) + 3\ H_2O(l) = 4\ HF(aq) + H_2SO_3(aq)$	[c]	179.0[11]	180.8
5-8	Appearance Potentials[d]	$SF_6(g) = SF_4(g) + 2\ F(g)$	145.0 ± 4.6(0)	181.6 ± 5.0	
8	Appearance Potentials[e]	$NSF_3(g) + F(g) = SF_4(g) + N(g)$	17.5(0)	161.8	
9	Appearance Potentials[f]	$SF_6(g) = SF_4(g) + 2\ F(g)$	116.2(0)	210.4	

[a]Auxiliary $\Delta_f H°(298.15\ K)$ data in kcal·mol^{-1}: $NSF_3(g)$, −85.2 ± 0.5;[1] HF(l), −72.37.[2, 10]
[b]Results reduced with HF PVT and calorimetric data from.[10]
[c]Hydrolysis data unavailable; $\Delta_f H°$ value from[11] adjusted for changes in $\Delta_f H°$ of HF(aq).
[d]Ion Processes: $SF_6(g) + e^- = SF_4^+(g) + 2\ F(g) + 2\ e^-$ $SF_4(g) + e^- = SF_4^+(g) + 2\ e^-$
[e]Ion Processes: $SF_4(g) + e^- = SF_3^+(g) + F(g) + 2\ e^-$ $NSF_3(g) + e^- = SF_3^+(g) + N(g) + 2\ e^-$
[f]Ion Processes: $SF_5(g) + e^- = SF_4(g) + F\ (g)$ $SF_5(g) + e^- = SF_5\ (g)$ $SF_6(g) + e^- = SF_5\ (g) + F(g)$

All of these studies are relatively imprecise, suggesting the need for an unequivocal redetermination of $\Delta_f H°$. Both calorimetric results[3, 4] are based on measurements made with impure samples (−98% SF_4) and suffer from the additional uncertainties introduced by the formation of HF. The ionization processes involve unknown kinetic and excitation energies, as evidenced by the widely scattered results. The first three $\Delta_f H°$ values listed above are reasonably consistent; thus, we are led to adopt their mean value of $\Delta_f H°(SF_4, g, 298.15\ K) = -182.4$ kcal·mol^{-1}. The estimated uncertainty is ± 5.0 kcal·mol^{-1}. Our $\Delta_f H°$ value corresponds to a enthalpy of atomization and average bond dissociation energy of 320.1 and 80.0 kcal·mol^{-1}, respectively.

Heat Capacity and Entropy

Detailed structural data determined by electron diffraction[14] and microwave spectroscopy[15] show good agreement. We arbitrarily adopt the microwave data which indicate a trigonal bipyramid structure with two inequivalent sets of fluorine atoms. The inequivalence of the fluorines is also supported by nuclear resonance[16, 17] and x-ray photoelectron spectroscopic[18, 19] studies. The principal moments of inertia are: $I_A = 12.5525 \times 10^{-39}$, $I_B = 20.5464 \times 10^{-39}$ and $I_C = 26.0707 \times 10^{-39}\ g \cdot cm^2$.

Various spectroscopic methods have been used to study the vibrational spectrum of SF_4. These studies include crystal,[20] liquid[21] and gas[22] phase Raman and gas[21-23] phase and argon matrix isolation[24] infrared spectra. The measured frequencies show good agreement but various interpretations of the observed spectra have been presented. We choose to adopt the results of the latest interpretation by Levin.[20] It should be noted that the vibrational assignments are immaterial for the purpose of evaluating the thermal functions since none of the fundamentals are degenerate. MO calculations[25] predict a singlet ground state with no excited states lying at energies which would be significant in the statistical calculations.

Our thermal functions essentially extend and update those reported by O'Hare[11] but are in disagreement with other literature data.[26, 27] The functions reported by Radhakrishnan[26] are based on an incorrect structure and older vibrational frequencies.[21] The set of frequencies used by Wilkins[27] are very similar to ours but his moments of inertia appear unrealistic. We conclude that his thermal functions[27] are erroneous.

Enthalpy of Formation

The electron–impact AP of SF_4^+ from SF_4 has been reported as 12.28 ± 0.03 eV,[1] 12.08 ± 0.1 eV,[2] and 12.1 ± 0.5 eV.[2] Using the mean value (12.15 eV) of these three measured AP as $\Delta_r H°(0\ K)$ for the direct ionization process $SF_4(g) + e^- \rightarrow SF_4^+ + 2\,e^-$, we obtain the adopted value $\Delta_f H°(SF_4^+, g, 0\ K) = 99.3\ kcal \cdot mol^{-1}$, by combining $\Delta_f H°(0\ K)$ with $\Delta_f H°(SF_4, g, 0\ K) = -180.9 \pm 5.0\ kcal \cdot mol^{-1}$.[3] We estimate that the adiabatic AP (or IP) could be as much as 0.3 eV lower than the measured vertical values,[1,2] suggesting uncertainties in $\Delta_r H°(0\ K)$ and $\Delta_f H°(0\ K)$ of ±7.0 $kcal \cdot mol^{-1}$ and ±12.0 $kcal \cdot mol^{-1}$, respectively. Our predictions are based on the fact that photoelectron studies[4] on the species ClF_3 show that the first adiabatic ionization potential is 0.23 eV lower than the vertical value and 0.35 eV lower than the results obtained by the electron–impact method. The similarity in the structures of SF_4 and ClF_3 has been noted,[5] and we predict that the geometry changes produced by ionization should also be very similar for the two fluorides.

Additional information is available which tends to provide some support for our adopted value of $IP(SF_4) = 12.15 \pm 0.3$ eV. Fehsenfeld[6] has observed a charge–transfer reaction between SF_4^+ and NO which sets the lower limit of IP at 9.25 eV. Binding energies[7] for SF_4 and SF_4^+, computed by CNDO/2 calculations and rescaled according to energy partitioning concepts, have been combined to give IP values of 11.1 eV and 10.6 eV. Three independent measurements[2,8,9] of the fragment–ion AP for SF_4^+ from SF_6 are in agreement with the result AP = 18.61 eV. We combine this $AP(SF_4^+/SF_6)$ with our adopted IP value and obtain $\Delta_r H°(0\ K) = 149.0\ kcal \cdot mol^{-1}$ for the process $SF_6(g) = SF_4(g) + 2F(g)$. This leads to a $\Delta_f H°$ of $-176.2\ kcal \cdot mol^{-1}$ for SF_4 which compares favorably with JANAF data.[3]

$\Delta_f H°$ is calculated to be 99.4 $kcal \cdot mol^{-1}$ at 298.15 K. Also, we find that the primary bond dissociation energy $D_0°(SF_3^+–F)$ is 12.9 $kcal \cdot mol^{-1}$ which when compared with $D_0°$ values[3] for SF_4 (80.0 $kcal \cdot mol^{-1}$) and SF_4^- (46.6 $kcal \cdot mol^{-1}$) indicates that the trend is $D_0°(SF_4) >> D_0°(SF_4^-) >> D_0°(SF_4^+)$. The observed instability of the radical cation towards dissociation to SF_3^+ and F is consistent with ion abundances[9,10] obtained for SF_4^+ and SF_3^+ in the mass spectra of SF_5Cl and SF_6. Values of the ratio $I(SF_3^+)/I(SF_4^+)$ lie in the range 3.1–7.0. (See the $SF_3^+(g)$ table for a discussion on its stability.) The enthalpy of atomization and mean bond dissociation energy are 278.8 $kcal \cdot mol^{-1}$ and 69.7 $kcal \cdot mol^{-1}$, respectively.

Heat Capacity and Entropy

Delwiche[8] has reported an ionization efficiency curve for SF_4^+ which was obtained from retarded potential difference (RPD) measurements on SF_6. This curve shows the existence of two excited states, lying 26213 cm^{-1} and 45167 cm^{-1} above the ground state. The level at 45167 cm^{-1} is not included here since it has a negligible effect on the thermal functions. We assume that the one unpaired electron forms two doublet states which are non–degenerate.

The ESR spectrum[11] of SF_4^+, recorded during the radiolysis of SF_6 with 2.8 MeV electrons, suggests that the four fluorine nuclei are equivalent. However, the assignment of this spectrum to SF_4^+ has been questioned by Morton and Preston[12] who presented evidence which indicates that the radical responsible is more likely be be SF_5. Their re–assignment[12] is substantiated by the results of SCF MO calculations[13] on SF_5. By analogy with the isoelectronic radical PF_4,[14,15] we predict that the SF_4^+ structure is trigonal bipyramid with the unpaired electron occupying one of the equatorial positions. We use bond angles from PF_4[14] and assume that the loss of an electron from SF_4 increases both the equatorial and axial bond lengths by 5%. Our view that the bonding in SF_4^+ is weaker than that in SF_4 follows the predictions[14] made for PF_4 and is further confirmed by the fact that the mean bond dissociation energy in SF_4 (80.0 $kcal \cdot mol^{-1}$) is roughly 10 $kcal \cdot mol^{-1}$ greater than in SF_4^+ (69.7 $kcal \cdot mol^{-1}$). The individual moments of inertia are: $I_A = 14.2509 \times 10^{-39}$, $I_B = 22.1083 \times 10^{-39}$, and $I_C = 29.8073 \times 10^{-39}\ g \cdot cm^2$.

We estimate vibrational frequencies from those for SF_4[3] by considering the effect of the structural changes brought about by ionization. On going from SF_4 to SF_4^+, we expect a decrease in all frequencies to reflect the weaker bonding in the cation.

Enthalpy of Formation

We adopt $\Delta_f H°(SF_4^-, g, 0\ K) = -209.8 \pm 8.0$ kcal mol^{-1} and $EA(SF_4) = 1.25 \pm 0.56$ eV. The value of $\Delta_f H°(0\ K)$ is obtained from the electron–impact appearance potential for SF_4^- from SF_6, reported by Harland and Thynne[1] as AP = 5.0 ± 0.1 eV. This value has been verified in an independent study.[9] We assume that the negative ion is formed by the process $SF_6(g) + e^- = SF_4^-(g) + 2\ F(g)$ with no excess energies. We estimate the error in the electron–impact experiments to be ±0.3 eV (7.0 kcal mol^{-1}) which when combined with the uncertainties in the auxiliary data[2] gives an overall uncertainty in $\Delta_f H°(0\ K)$ of ±8.0 kcal mol^{-1}. Our adopted value of EA = 1.25 eV is supported by EA = 1.5 eV[3] and EA = 1.26 eV[10] which were predicted by theoretical calculations.

In the same paper, Harland and Thynne[1] also reported the $AP(SF_4^-/SF_5Cl)$ as 4.1 ± 0.1 eV. This leads to $\Delta_f H°(SF_4^-, g, 0\ K) = -199.9 \pm 5.0$ kcal mol^{-1} and $EA(SF_4) = 0.82 \pm 0.4$ eV. They[1] also reported appearance potentials for SF_3^- and SF_5^- from SF_5Cl which give EA values that are several tenths of an electron volt below JANAF data.[2] Thus, we are led to conclude that dissociative ionization of SF_5Cl probably involves excess energies and that the derived electron affinities are lower limit values.

Our adopted results give $\Delta_f H°(298.15\ K) = -212.1$ kcal·mol^{-1} and a fluoride-ion affinity (IA) of $IA(SF_3) = 30.5$ kcal·mol^{-1}. Also, we find that the primary bond dissociation energy $D_0°(SF_3^- – F)$ is 46.6 kcal·mol^{-1} which when compared with $D_0°$ values[2] for SF_4 (80.0 kcal·mol^{-1}) and SF_4^+ (12.9 kcal·mol^{-1}) indicates that the trend is $D_0°(SF_4) >> D_0°(SF_4^-) >> D_0°(SF_4^+)$. These thermochemical predictions of the SF_4^- stability are consistent with an autodetachment lifetime of 16.3 μsec, as measured by Harland and Thynne[4] using time–of–flight techniques. The enthalpy of atomization ($\Delta_{at}H°$) for the products S(g) + F^-(g) + 3 F(g) and mean bond dissociation energy are 270.5 kcal·mol^{-1} and 67.7 kcal·mol^{-1}, respectively.

Heat Capacity and Entropy

We assume a square–planar configuration (D_{4h} symmetry) similar to that found for the isoelectronic radical ClF_4.[5-7] We estimate the bond length to be slightly greater (0.03Å) than the mean (1.60Å) of the equatorial and axial S–F bonds in SF_4.[2] An upper limit of 1.70Å can be established from results of MO calculations on ClF_4.[7] The individual moments of inertia are: $I_A = 3.3526 \times 10^{-38}$ and $I_B = I_C = 1.6763 \times 10^{-38}$ g·cm^2.

The square–planar structure follows the vibrational representation $A_1 + A_2 + 2B_1 + B_2 + 2E$. We estimate the seven fundamentals by comparison with the observed frequencies for the approximately square–planar SF_4 part of SF_5^-.[2] Comparison of the experimentally measured frequencies for the related species ClF_5[2] and ClF_4^- [8] suggests that this procedure should give reliable estimates.

The electronic states and levels are based on those for ClF_4 which were predicted by Ungemach and Schaefer[7] from MO calculations. An independent MO study of ClF_4 by Gregory[6] indicates that the upper level is an $^2A_2$ state. This, however, would not alter our functions since both configurations have the same degeneracy.

264.2(2)	388.7(3)

Ground State Quantum Weight: [1] $\sigma = 12$

Point Group: T_d

Bond Distance: Si–F = 1.552 ± 0.002 Å

Bond Angle: F–Si–F = 109° 28'

Product of the Moments of Inertia: $I_A I_B I_C = 8.321027 \times 10^{-114}\ g^3 \cdot cm^6$

Enthalpy of Formation

The adopted $\Delta_f H°(SiF_4, g, 298.15\ K) = -385.98 \pm 0.20\ kcal \cdot mol^{-1}$ is the result of measurement of the direct combination of the elements in a bomb calorimeter by Wise *et al.*[1] and is the value recommended by CODATA.[2] Bousquet *et al.*[3] determined $\Delta_f H°(298.15\ K) = -385 \pm 4\ kcal \cdot mol^{-1}$, also by fluorine combustion calorimetry, which is less precise but is in agreement with the adopted value. An average result, $\Delta_f H°(298.15\ K) = -372.4 \pm 0.4\ kcal \cdot mol^{-1}$ by Vorob'ev *et al.*[4] from the reaction of $SiF_4(g)$ and Na(cr) and from two rather involved enthalpy of solution schemes, is not used.

Using JANAF auxiliary values,[5] $\Delta_{at} H°(0\ K) = 564.76 \pm 3\ kcal \cdot mol^{-1}$ is calculated for the process $SiF_4(g) = Si(g) + 4\ F(g)$.

Heat Capacity and Entropy

The four fundamental vibrational frequencies are adopted from the vapor–phase Raman spectral investigation of Clark and Rippon.[6] Jones *et al.*[7] photographed the Raman spectrum of the liquid and assigned values of 800, 268, 1010, and 390 cm^{-1} to the four fundamental vibrational frequencies. Yost *et al.*[8] determined only ν_1 at 800 cm^{-1} Shimanouchi[9] references four articles including that of Jones *et al.*[7] and has selected 800, 268, 1032, and 389 cm^{-1}. All of these assignments are in good agreement.

The interatomic distances from electron diffraction studies were found to be 1.555 ± 0.002 and 2.534 ± 0.003 Å for Si–F and F...F, respectively, by Beagley *et al.*[10] and 1.552 ± 0.002 and 2.534 ± 0.003 Å by Hagen and Hedberg.[11] The value of Si–F = 1.552 ± 0.002 Å is adopted because it is in agreement with the F...F distance and the tetrahedral bond angle. The three principal moments of inertia are: $I_A = I_B = I_C = 20.2640 \times 10^{-39}\ g \cdot cm^2$.

Our calculation of $S°(298.15\ K) = 67.55 \pm 0.10\ cal\ K^{-1} \cdot mol^{-1}$ agrees with the value recommended by CODATA.[2]

$S°(298.15\ K) = 133.955\ J \cdot K^{-1} \cdot mol^{-1}$
$T_{fus} = 558.6\ K$

$\Delta_f H°(0\ K) = -1647.108 \pm 3.8\ kJ \cdot mol^{-1}$
$\Delta_f H°(298.15\ K) = -1649.333 \pm 3.8\ kJ \cdot mol^{-1}$

Enthalpy of Formation

The enthalpy of formation of TiF_4(cr) was measured using a fluorine bomb calorimeter by Greenberg *et al.*[1] Gross *et al.*[2] reported a value of $-393.4\ kcal \cdot mol^{-1}$ for $\Delta_f H°(298.15\ K)$. The latter measurements were not corrected for impurities in the titanium sample, thus the value reported by Greenberg *et al.*[1] is adopted.

Heat Capacity and Entropy

The heat capacity of TiF_4(cr) has been measured over the temperature range 6 to 304 K by Euler and Westrum.[3] They obtained the value of $S°(298.15\ K)$ based on $S°(10\ K) = 0.11\ cal\ K^{-1} \cdot mol^{-1}$. Heat capacities above 300 K are estimated from those of ZrF_4(cr).[4]

Sublimation Data

The sublimation point is calculated as the temperature at which the fugacity is one atmosphere for the process $TiF_4(cr) = TiF_4(g)$. The enthalpy of sublimation is obtained from the data of Hall *et al.*[5]

Enthalpy of Formation

The enthalpy of formation of $TiF_4(g)$ is calculated from that of the crystal and the enthalpy of sublimation, $\Delta_{sub}H°(298.15\ K)$, obtained from vapor pressure measurements. Hall *et al.*[1] have reported extensive vapor pressure data for the reaction $TiF_4(cr) = TiF_4(g)$. 2nd and 3rd law analyses of their data yielded the following results.

Method	Data Points	T/K	$\Delta_r H°(298.15\ K)$, $kcal·mol^{-1}$ 2nd law	3rd law	Drift cal $K^{-1}·mol^{-1}$	$\Delta_f H°(298.15\ K)$* $kcal·mol^{-1}$

*** Eight points rejected due to failure of a statistical test.

Heat Capacity and Entropy

The interatomic distance is obtained from a correlation of the measured values for $TiCl_4(g)$, $TiBr_4(g)$, $TiCl_6$,[-2] and TiF_6.[-2] The principal moments of inertia are $I_A = I_B = I_C = 27.2575 \times 10^{-39}\ g·cm^2$.

The vibrational frequencies are estimated by a valence force field treatment of estimated force constants. The force constants are estimated from a correlation with the constants of CF_4, SiF_4, CCl_4, $SiCl_4$, CBr_4, $SiBr_4$, $TiCl_4$, and $TiBr_4$. The resulting frequencies are adjusted so that calculations of $\Delta_{sub}H°(298.15\ K)$ by both 2nd and 3rd law methods are in agreement.

$\Delta_{fus} H° = 64.224 \pm 0.42\ kJ \cdot mol^{-1}$

Enthalpy of Formation

The enthalpy of formation of zirconium tetrafluoride was measured by direct combination of the elements in a bomb calorimeter by Greenberg *et al.*[1] The reported value, $\Delta_f H°(ZrF_4, cr, 298.15\ K) = -456.80 \pm 0.25\ kcal \cdot mol^{-1}$, is adopted.

Heat Capacity and Entropy

The low temperature heat capacities in the temperature range 5 to 307 K were determined by adiabatic calorimetry by Westrum.[2] Using these low temperature $C_p°$ data the value of $S°(298.15\ K)$ is derived as 25.024 ± 0.05 cal $K^{-1} \cdot mol^{-1}$ based on $S°(10\ K) = 0.0074$ cal $K^{-1} \cdot mol^{-1}$.

McDonald *et al.*[3] measured the high temperature enthalpies of ZrF_4(cr) at temperatures 283.9–1225.8 K in a copper block drop calorimeter. Smith *et al.*[4] used a Bunsen ice calorimeter for the enthalpy measurements in the temperature range 273–1150 K. These two sets of enthalpy data are not in good agreement. It is possible that the discrepancies are due to the difference in crystal structure of the samples used (see "Transition Data" for more information). In order to join smoothly with the low temperature heat capacities at 298.15 K, the high temperature heat capacities derived from the enthalpy data of McDonald *et al.*[3] are adopted. The $C_p°$ values above 1200 K are obtained by smooth extrapolation.

Fontana and Winand[8] also measured the enthalpy of ZrF_4 in the range 773–1350 K. Their reported average heat capacity in this range and their reported enthalpies are considerably lower than those adopted.

Transition Data

Gaudreau[5] presented evidence that ZrF_4 has three crystal structures (α, β, and) and one amorphous form. Chretien and Gaudreau[6] found that ZrF_4(cr) has an α (tetragonal) and β (monoclinic) form with a transition temperature of $T_{trs} = 723$ K. The crystal data compilation of Donnay and Ondik[7] tabulated two monoclinic structures for ZrF_4; one of which was specified as the β form while no mention was made of a tetragonal form.

The ZrF_4 sample employed by McDonald *et al.*[3] for enthalpy measurement was prepared by dissolving hafnium–free zirconium metal in 48% aqueous HF, and the resulting solution was evaporated to dryness. The crystalline product was heated slowly to 773 K in a platinum boat in a slow current of anhydrous HF. X–ray diffraction showed only crysalline ZrF_4. Wet analysis indicated 54.6% Zr (theory 54.55) and 44.9% F (theory 45.45). Due to the above facts we are uncertain whether the sample prepared is a mixture of α and β forms of a pure $ZrF_4(\beta)$. Smith *et al.*[4] obtained their ZrF_4 sample from the Oak Ridge National Laboratories, Oak Ridge, Tenn. Since the method of preparation of the compound is unavailable from the report, we do not know what kind of sample they used for measurement.

Because of the above unresolved situation, we emphasize that this ZrF_4(cr) table is not strictly a α, β-combined phase table. However, the differences in the calculated functions are probably not significant.

Fusion Data

T_{fus} and $\Delta_{fus}H°$ are taken from McDonald *et al*[3]. The values were obtained under conditions greater than one atmosphere. Fontana and Winand[8] reported a heat of melting of 11.81 ± 2.40 kcal $\cdot mol^{-1}$ (under pressure).

Sublimation Data

The sublimation temperature ($T_{sub} = 1179$) is calculated as the temperature at which the fugacity is one atmosphere for the process $ZrF_4(cr) = ZrF_4(g)$. Since the sublimation temperature is lower than the melting point, the ZrF_4 sublimes before it melts.

Enthalpy of Formation

The vapor pressures of ZrF_4(cr) in the temperature range 617–1150 K were determined by many investigators using various methods. Based on the reported vapor pressure data, the corresponding enthalpies of sublimation are evaluated by the 2nd and 3rd law methods. Using the 3rd law $\Delta_{sub}H(298.15\ K)$ and $\Delta_f H°(ZrF_4, cr, 298.15\ K) = -456.8\ kcal \cdot mol^{-1}$, the enthalpies of formation at 298.15 K for ZrF_4(g) are evaluated. The results are presented in the table below. The values of $\Delta_f H°(ZrF_4, g, 298.15\ K)$, listed in the last column of this table are in excellent agreement which indicate that the estimated missing vibrational frequencies ν_1 and ν_2 are reasonable. The enthalpy of formation at 298.15 K for ZrF_4 (g) is adopted as $-400.0\ kcal \cdot mol^{-1}$.

Heat Capacity and Entropy

The molecular structure of ZrF_4(g) has been studied by electron diffraction by Spiridonov.[11] The configuration was found to be a regular tetrahedron with interatomic distance Zr–F = 1.94 ± 0.02 Å and F–Zr–F bond angle = 109.47° which are adopted.

Employing the estimated interaction coefficients and interatomic distance Zr–F = 1.85 Å, Godnev *et al.*[12] calculated three vibrational frequencies for ZrF_4(g) as ν_2 = 150–200, and $\nu_4 = 180 \pm 230\ cm^{-1}$. Bucher *et al.*[13] observed the infrared spectra of some group IV halides and assigned $\nu_3 = 668$ and $\nu_4 = 190 \pm 20\ cm^{-1}$ for ZrF_4 (g). The frequency ν_3 has also been reported as $670\ cm^{-1}$.[14] In studying matrix isolated ZrF_4, Hauge *et al.*[15] found a strong infrared band at 668.0 cm^{-1} in an argon matrix and 677.0 cm^{-1} in a neon matrix; both of which were attributed to the ν_3 stretch frequency. The values of ν_3 and ν_4 adopted here are those reported by Buchler *et al.*[13] The adopted ν_1 is obtained by correlating the corresponding frequencies of the tetrafluorides of C, Pb, Si, Ti and Ge with their respective interatomic distances. ν_2 is calculated from ν_1, ν_3 and ν_4 usng the relationship[15] $\nu_3\nu_4/\nu_1\nu_2 = 2/3 + 4$ F/Zr where F and Zr are gram atomic weights of fluorine and zirconium, respectively. Vibrational frequencies (635, 178, 668, and 190 cm^{-1}) were suggested by Godnev *et al.*[12] who also critically examined the sublimation data in order to achieve internal consistency. These values are in good agreement with our adopted values. The three principal moments of inertia are $I_A = I_B = I_C = 31.6625 \times 10^{-39}\ g \cdot cm^2$.

Ground State Quantum Weight: 1 σ = [5]

Point Group: [C_5]

Bond Distance: F–F = [2.5] Å

Product of the Moments of Inertia: $I_A I_B I_C = [1.059909 \times 10^{-112}]\ g^3\cdot cm^6$

Enthalpy of Formation

The enthalpy of 5 HF(g) → H_5F_5(g) was taken as the mean of the 3rd law values which were determined from the equilibrium data of two investigations. Briegleb and Strohmeier[1] measured the vapor density of associated HF between 20 and 60°C and between 50 and 650 torr. Franck and Meyer[2] measured $C_p°$ between −20 and 100°C and between 100 and 700 torr. Each investigation evaluated K_p at n = 2, 3, 4, ... for the reactions n(HF) → $(HF)_n$ and reported 2nd law values of $\Delta_f H$ and $\Delta_f S$. At n = 5 their 2nd law values differed by 5.2 $kcal\cdot mol^{-1}$, which was taken as an estimate of error, while the calculated 3rd law values differed by 3.1 $kcal\cdot mol^{-1}$. Using $\Delta_f H°(298.15\ K) = -30.35\ kcal\cdot mol^{-1}$ and auxiliary JANAF data[3] gives the enthalpy of formation of H_5F_5(g).

Heat Capacity and Entropy

The molecular structure of H_5F_5 was assumed as planar with the F atoms forming the vertices of a regular pentagon and with the H atoms also lying on the circumscribed circle. That rings are more stable than open chains was confirmed by Del Bene and Pople's[4] theoretical molecular-orbital studies on HF polymers. The length of side (F–F axis) was taken from Atoji and Lipscomb's[5] X-ray studies of solid HF (F–F = 2.49 Å) and agrees with the 2.52 Å which Janzen and Bartell[6] determined for HF gaseous polymers by electron diffraction. The low F–bending frequency (53 cm^{-1}) was taken from Boutin *et al.*)[7] The other vibrational frequencies were taken from Kittelberger and Hornig's[8] work on crystalline HF. Huong and Couzi[9] and Smith[10] have made spectral studies of the gas phase in the range from 350 to 4000 cm^{-1}.

The National Bureau of Standards prepared this table[11] by critical analysis of data existing in 1972. Using molecular constants and $\Delta_f H°$ selected by NBS,[11] we recalculate the table in terms of 1973 fundamental constants,[12] 1975 atomic weights,[13] and current JANAF reference states for the elements.

Enthalpy of Formation

The adopted value is derived from calorimetric data of Settle *et al.*[1] for the combustion of iodine in fluorine. Although the combustions gave various mixtures of IF_5 and IF_7, the proportions ranged up to almost pure pentafluoride. Reduction of the data gave $\Delta_f H° = -210.80 \pm 0.32$ kcal·mol^{-1} for IF_5(l) at 298.15 K. The result is essentially independent of the heptafluoride.

Comparison values of $-208.9 \pm [>1]$ and $-208.8 \pm [>1.7]$ kcal·mol^{-1} may be obtained from calorimetric data of Woolf[2] for hydrolysis in water and in aqueous KOH. Uncertainties for these values include large contributions due to auxiliary data.[3] In particular, we estimate lower limits of ±0.8 kcal·mol^{-1} for $\Delta_f H°$ of HIO_3(1250 H_2O) and KIO_3(1250 H_2O) by comparison with recent data.[4]

$\Delta_f H°$ for the ideal gas is derived from that of the liquid by use of $\Delta_{vap} H° = 9.96$ kcal·mol^{-1} at 298.15 K. $\Delta_{vap} H°$ was derived by Osborne *et al.*[5] from measurements of vapor pressure and the second virial coefficient.

Heat Capacity and Entropy

There is no published structural determination for gaseous IF_5, but spectral data are consistent with C_{4v} symmetry and a configuration which is approximately a square pyramid. It is uncertain whether the iodine is located above, in, or below the base of the pyramid and whether or not the axial and equatorial I–F distances are equal. We adopt the structure used by Begun *et al.*[7] in correlation of infrared and Raman spectra of BrF_5, IF_5, ClF_5, and $XeOF_4$ by normal coordinate analysis. In this structure the axial bond length is shorter than the equatorial length and the values are close to those observed experimentally for IF_7. The iodine is presumed to be in the base of the pyramid. Simplified Huckel–molecular–orbital calculations[8] predict that C_{4v} is the most stable symmetry, that the axial bond is shorter, and that the equatorial flourines are distorted toward the axial fluorine. It is not clear to what extent these predictions depend on the simplified HMO model used in the calculations. Begun *et al.*[7] note that the normal coordinate calculations are insensitive to changes in the bond angles. Principal moments are $I_A = 43.6575 \times 10^{-39}$, $I_B = I_C = 30.6631 \times 10^{-39}$ g·cm^2.

Vibrational frequencies are based on the assignments of Begun *et al.*[7] as modified by the vapor–phase Raman spectra observed by Selig.[6] Location of the band center of ν_9(~200 cm^{-1}) is difficult, so we substitute the liquid value of 190 cm^{-1}. The Raman–active fundamental ν_5 is not observed for IF_5 or any of the similar molecules, so its value is taken from the calculations.[7] Osborne *et al.*[5] used calorimetric data at low temperatures to derive $S° = 57.96 \pm 0.06$ cal $K^{-1} \cdot mol^{-1}$ for the liquid at 330 K. Combining this with $\Delta_{vap} S°$ based on their vapor pressure equation, the authors obtained $S° = 83.06 \pm 0.20$ cal $K^{-1} \cdot mol^{-1}$ for the ideal gas at 330 K. The corresponding value from this table (82.50) is lower by 0.56 cal $K^{-1} \cdot mol^{-1}$. Part of this difference arises from uncertainties in ν_5 and ν_9 the product of the moments of inertia. We estimate this uncertainty at about 0.5 cal K·mol^{-1}. Another source of minor uncertainty is the neglect of anharmonicity in the calculations.

Enthalpy of Formation

We adopt the enthalpy of formation at 298.15 K derived by Brewer[1] from the high temperature mass spectrometric measurements of equilibria among gaseous molybdenum fluorides by Hildenbrand [1143–1664 K][2] and by Kleinschmidt *et al.* [460–525 K].[8] The value of $\Delta_f H°(0\ K)$ combined with JANAF data[3] for Mo(g) and F(g) gives $\Delta_{at} H°(0\ K) = 544.3 \pm 4\ kcal·mol^{-1}$ and an average Mo–F bond energy of $\Delta_{at} H°(0\ K)/5 = 108.9 \pm 1\ kcal·mol^{-1}$.

Heat Capacity and Entropy

Hildenbrand,[4] Douglas,[5] and Krause[6] have calculated somewhat different thermodynamic properties of $MoF_5(g)$ monomer. All have used the vibrational frequencies, cm^{-1}, and degeneracies determined by Acquista and Abramowitz[7] —759,[1] 738,[1] 683,[1] 713,[2] 261,[2] and 112[2] — and an estimated frequency of 500.[1] For the remaining doubly degenerate frequency, Hildenbrand[4] estimated 200 cm^{-1} and both Douglas[5] and Drause[6] estimated 400 cm^{-1}. We follow Brewer[1] who has used the determined vibrational frequencies and the estimated frequencies [500][1] and [200],[2] as had Hildenbrand.[4]

From the following analysis, Brewer[1] has attempted to define the electronic contribution more accurately then just a ground state degeneracy of 2.[4,5] or 4.[6] Mo^{5+} has only the low-lying electronic state ^2D with a spin orbit splitting of 2578 cm^{-1} and a total degeneracy of 10. From the liquid field treatment of ReF_6 by Moffitt *et al.*,[9] one might expect an intermediate coupling case with a $t_{3/2}$ quartet ground state and a low-lying $t_{1/2}$ state, with the next quartet state well above 20000 cm^{-1}. Peacock and Sleight[10] observed an absorption in liquid MoF_5 at 7500 cm^{-1}. For MoF_5 monomer, the actual levels would be split more. On this basis, the following electronic energy levels, cm^{-1}, and quantum weights were assigned:[1] 0,[2] [1000],[2] [7500],[2] and [25000].[4]

The trigonal bipyramid symmetry tentatively assigned by Acquista and Abramowitz[7] is used with the Mo–F distance of 1.78 Å adopted by Brewer.[1] The principal moments of inertia are: $I_A = 29.9871 \times 10^{-39}\ g\ cm^2$, $I_B = I_C = 34.9849 \times 10^{-39}\ g·cm^2$.

This table is based on the critical analysis of data existing in 1978 by Brewer [1].

Enthalpy of Formation

Gross *et al.*[1] measured the heat of combustion of α–white phosphorus in fluorine at 25 °C. They reported an enthalpy of formation of -381.4 ± 0.8 kcal·mol^{-1} (based on α–white phosphorus standard state) calculated from their combustion studies. Similar combustion studies were performed by O'Hare and Hubbard.[2] They reported a enthalpy of formation of -380.8 ± 0.3 kcal·mol^{-1} (α– white phosphorus standard state), which is in excellent agreement with the work of Gross *et al.*[1] An average value of -381.1 ± 0.5 kcal·mol^{-1} is adopted for this tabulation. Converting to the P(red,V) standard state with a $\Delta_f H$ trans = 4.2 ± 0.2 kcal·mol^{-1},[3] we derive, $\Delta_f H°(PF_5, g, 298.15\ K) = -376.9 \pm 0.7$ kcal·mol^{-1} (-1576.950 ± 2.9 kJ·mol^{-1}).

Heat Capacity and Entropy

The molecular structure and bond lengths given above for PF_5 were recently determined by Hansen and Bartell[4] from electron–diffraction studies. These results indicate that PF_5 has a trigonal bipyramid structure with nonequivalent axial and equatorial bonds. Wyatt *et al.*[5] determined rotational constants for PF_5 from a study of the infrared vibration–rotation band contour of the ν_4(575 cm^{-1}) fundamental. Their analysis led to the following P–F bond lengths which are in excellent agreement with the electron–diffraction results: $r_{eq.} = 1.534 \pm 0.024$Å and $r_{ax.} = 1.581 \pm 0.025$Å. Individual moments of inertia, calculated from the rotational constants given by Wyatt *et al.*[5] and adopted for this table, are $I_A = 2.230 \times 10^{-38}$ g cm^2 and $I_B = I_C = 2.690 \times 10^{-38}$ g cm^2. The electron diffraction data lead to a product of moments of inertia of $1.604 \times 10^{-113}\ g^3 \cdot cm^6$.

Several recent infrared and Raman studies[6,7,8] have been reported for PF_5. These data are in good agreement except for the ν_7 fundamental. Griffiths *et al.*[6] originally assigned this fundamental to the 126 cm^{-1} band observed in their infrared spectra. Hoskins[9] later attributed this band to one of the pure rotational lines of hydrogen fluoride, which he felt was present in the sample as an impurity. Further work by Griffiths[10] on the pressure dependence of the infrared spectra of PF_5 indicated that the missing fundamental should be assigned to the weak band at 301 cm^{-1}. Deiters and Holmes[11] recently showed that this band is not a fundamental of PF_5 but a difference band (ν_3–ν_2). Very recently, Levin[8] investigated the Raman spectra of solid phosphorus pentafluoride and assigned the ν_7 fundamental to the 179 cm^{-1} band. Also, Beattie *et al.*[12] investigated the Raman spectra of PF_5 in the gas phase at 25°C and 125°C and assigned the ν_7 fundamental to 175 cm^{-1} band which is in excellent agreement with Levin's assignment.[8] The fundamental vibrational frequencies of Holmes and Lord[7] are adopted along with Levin's assignment[8] of the ν_7 fundamental (179 cm^{-1}).

Enthalpy of Formation

$\Delta_f H°(0\ K)$ is calculated from the bond dissociation process $SF_6(g) = SF_5(g) + F(g)$ with $D_0° = 92.0 \pm 3.0$ kcal·mol^{-1} and JANAF auxiliary enthapies of formation.[1] The information which was considered in arriving at the selected $D_0°$ value is reviewed below. Another recent review[2] of the thermodynamics of SF_5 led to selected values of $D_0°(SF_5–F) = 92.6 \pm 3.0$ kcal·mol^{-1} and $\Delta_f H°(298.15\ K) = -218 \pm 3$ kcal·mol^{-1} which agree with the results adopted here.

The electron–impact appearance potential of F^- from SF_6 has been reported as approximately zero by Harland and Thynne[3] and Curran.[4] In addition, Curran[4] measured the kinetic energy of the negative ion and found K.E. (Total) = 0.23 ± 0.05 eV. Combining these results with EA(F) = 3.399 eV,[1] we obtain an upper limit value for $D_0°$ of <3.2 eV (73.1 kcal·mol^{-1}).

Modica[5] performed shock tube measurements on mixtures of SF_6/Ar, SF_5Cl/Ar, and SF_6/H_2 and analyzed the equilibrium data with a thermochemical equilibrium computer program. With $\Delta_f H°(SF_4, g, 0\ K) = -172.2$ kcal·mol^{-1}, Modica [5] adjusted the value of $\Delta_f H°$ for SF_5 to bring the calculated and experimental SF_4/HF concentrations into good agreement. These results suggest $\Delta_f H°(SF_5, g, 0\ K) = -241.7$ kcal·mol^{-1} or $D_0°(SF_5–F) = 65.2$ kcal·mol^{-1}. We are unable to reanalyze these shock tube equilibrium data but presumably the $\Delta_f H°$ and $D_0°$ values should be adjusted for the changes in $\Delta_f H°$ of SF_4.[1]

Bott and Jacobs[6] used infrared and ultraviolet absorption techniques to study the thermal (1650–2050 K) dissociation of SF_6 in a shock tube. They interpreted their rate data in terms of the RRK theory and showed that the results were consistent with $D_0°(SF–F) = 75.9 \pm 4.0$ kcal mol^{-1}. Lyman[7] has re-evaluated the SF_6 dissociation data in terms of the more complete RRKM unimolecular reaction rate theory and presented evidence which indicates that the $D_0°(SF_5–F)$ is considerably higher than previously reported. His analysis of the rate data yielded a $D_0°$ value of 92 kcal·mol^{-1} which we adopt.

The enthalpy of atomization and mean bond dissociation energy are calculated to be 372.2 kcal·mol^{-1} and 74.4 kcal·mol^{-1}, respectively. $\Delta_f H°(0\ K)$ combined with that for SF_5^+ [1] gives IP = 11.14 eV which appears reasonable in comparison with IP values for the other sulfur fluorides.[1]

Heat Capacity and Entropy

We assume that the five fluorine atoms form a tetragonal pyramid around the central sulfur atom based on evidence from an EPR study[8] which shows that four of the fluorine atoms are equivalent. This structure is further supported by recent SCF MO calculations[9] which predict that the F**–S–F* bond angle is near 90°. The geometry optimized bond lengths[9] appear to be about 0.2Å too large in comparison with experimentally measured S–F bond lengths for other sulfur–fluorine species.[1] We assume that the S–F* bond length is the same as that reported for SF_6 and S_2F_{10}.[1] The axial bond length is taken to be slightly shorter than the equatorial bonds, in accordance with the pattern followed in the related molecules ClF_5[12] and TeF_5^-.[10] The principal moments of inertia are: $I_A = 30.7102 \times 10^{-39}$ and $I_B = I_C = 21.4728 \times 10^{-39}$ g·cm^2.

Smardzewski and Fox[11] reported the matrix infrared spectra of SF_5 formed during the vacuum ultraviolet photolysis of SF_6 and its derivatives, SF_5X (X=F, Cl, Br, SF_5), in argon matrices at 8 K. Values of ν_7 and ν_8 are taken from this study. The other seven fundamentals are estimated by analogy with those for SF_5^- [1] and ClF_5.[12] Double (ν_1 and ν_7) and triple (ν_3, ν_4 and ν_8) coincidences are predicted at about 800 cm^{-1} and 550 cm^{-1}, respectively, based on the infrared spectra of ClF_5.[12] The four upper electronic levels are estimated from those observed for SF_6^+ [13] and are assummed to be doublets.

Our thermal functions essentially update and extend those previously reported by O'Hare.[14] Wilkins[15] has also calculated functions covering the temperature range 50–6000 K. He assumed that the structure of the radical was a trigonal bipyramid (D_{3h} symmetry). We cannot completely rule out this structure but consider it to be unlikely.

Enthalpy of Formation

The threshold energy for the formation of SF_5^+ from SF_6 has been measured by photoionization,[1] electron–impact,[2-5] and photoelectron spectroscopy.[4,6-8] Presented below is a summary of the reported appearance potentials (AP) along with results arrived at from an analysis of the data. Also included in the summary are results derived from an electron–impact study[9] on the formation of SF_5^+ from SF_5Cl. All auxiliary data are from the most recent JANAF tables[10] with the exception of the value for $\Delta_f H°(0\ K)$ of SF_5Cl. We use $\Delta_f H°(SF_5Cl, g, 0\ K) = -247.4\ kcal\cdot mol^{-1}$.

Source	Method	AP[a], eV	$\Delta_f H°(0K)$ $kcal\cdot mol^{-1}$	IP, eV

[a] $SF_6(g) + e^- = SF_5^+(g) + F(g) + 2\ e^-$ [b] $SF_5Cl(g) + e^- = SF_5^+(g) + Cl(g) + 2\ e^-$

No study has been made of the kinetic energies of the fragments produced by photoionization or electron–impact of SF_6 and SF_5Cl. As a result, the ionization potentials (IP) derived from these studies[1-5,9] represent upper limits to the true value. SF_5^+ is produced in the photoionization of SF_6 by rapid dissociation of SF_6^+ whose ground state is expected to exhibit Jahn–Teller instability.[1] As a result of this, an accurate determination of the threshold energy for the dissociation process is difficult. We choose to adopt a mean $\Delta_f H°(0\ K)$ value of 42.2 ± 5.0 $kcal\cdot mol^{-1}$ based on the results measured in four photoelectron spectroscopic studies[4,6-8] of the SF_6/SF_5^+ dissociation. Our adopted enthalpies of formation correspond to $IF(SF_5) = 11.14 \pm 0.37$ eV which is in agreement with the limiting values of 9.25<IP<12.05 eV.[13]

$\Delta_f H°$ is calculated to be 41.263 $kcal\cdot mol^{-1}$ at 298.15 K. Using JANAF data,[10] we find that the primary bond dissociation energy, $D_0°(SF_4^+-F)$, is 75.4 $kcal\cdot mol^{-1}$. This value appears reasonable in comparison with $D_0°$ values for other even–electron positive and negative S–F species,[10] providing some additional support for our adopted results.

Heat Capacity and Entropy

By anolog with SF_5[14,15] and SF_5^-,[10] we adopt a tetragonal pyramidal structure (C_{4v} symmetry). The SF_4 part of this configuration is predicted to be planar as a result of a reduction in the repulsive forces[16] upon ionization. The four equatorial S–F bond lengths are assumed equal to that for SF_3^+.[10] The axial bond length is assumed to be slightly shorter than the equatorial bonds, in accordance with the pattern followed in the related molecules ClF_5[10] and TeF_5^-.[17] The individual moments of inertia are: $I_A = 28.3933 \times 10^{-39}$ and $I_B = I_C = 19.9158 \times 10^{-39}\ g\cdot cm^2$. We estimate vibrational frequencies from those for SF_5,[10] SF_5^- [10] and ClF_5.[18] Double (ν_1 and ν_7) and triple (ν_3, ν_4, and ν_8) coincidences are predicted at 800 cm^{-1} and 550 cm^{-1}, respectively, based on the infrared spectra of ClF_5.[18] The electronic levels are calculated from the RPD measurements of Delwiche.[4] We do not include levels predicted to lie above 40,000 cm^{-1} since these have a negligible effect on the thermal functions. The existence of the first two excited states is verified by an independent RPD study.[3]

Enthalpy of Formation

The threshold energy for the dissociative electron attachment process $e^- + SF_6(g) = SF_5^-(g) + F(g)$ has been measured directly by means of mass spectrometry.[1-4] In addition, mass spectrometric studies[5] have been reported on various electron transfer reactions which provide independent estimates of the enthalpy for the above process. Presented below is a summary of the results derived from these measurements. Also included in the summary are results obtained from an electron–impact study[1] of the process $e^- + SF_5Cl(g) = SF_5^-(g) + Cl(g)$. We assume that the fragment–ions are formed in each process with no excess or kinetic energies. As a result, the derived electron affinities represent lower limits to the true value. Other reported values of $EA(SF_5)$ include >1.465 eV,[9] 3.2 eV[5] and 3.66 ± 0.04 eV.[10] The first two results are based on charge–transfer studies[5-9] while the latter value represents a direct measurement of EA using the magnetron technique.[10]

Source	Reaction	Method	AP or $\Delta_r H°(0\ K)$ kcal·mol^{-1}	$\Delta_f H°(SF_5^-, g, 0\ K)$[a] kcal·mol^{-1}	$EA(SF_5)$[a] eV
1	A	Electron–impact	2.31	−304.41	>3.89
2	A	RPD	1.15	−305.56	>3.94
3	A	RPD	5.77	−300.95	>3.74
4	A	Electron–impact	~0	−308.72	>3.99
5	A	Electron transfer	11.53	−295.19	>3.49
6	A	Collisional ionization	11.45	−295.07	>3.49
1	B	Electron–impact	4.61	−271.45	>2.46

Reactions: (A) $e^- + SF_6(g) = SF_5^-(g) + F(g)$ [a]Auxiliary $\Delta_f H°(0\ K)$ data (in kcal·mol^{-1}): SF_6,[7] − 288.36 ± 0.2; F,[7]
(B) $e^- + SF_5(g) = SF_5^-(g) + Cl(g)$ 18.36 ± 0.4; Cl,[7] 28.587; SF_5Cl,[8] −247.48; SF_5,[7] −214.7 ± 3.6.

We reject the electron–impact results on the dissociative electron attachment process for SF_5Cl since Harland and Thynne[1] also reported results for SF_5^- and SF_4^- which lead to EA that are too low.[7] The other results are reasonably consistent with the mean EA value of 3.7 ± 0.2 eV. This value corresponds to $\Delta_f H°(SF_5, g, 0\ K) = -300.0 \pm 8.0\ kcal·mol^{-1}$ which we adopt.

$\Delta_f H°$ (298.15 K) is −303.228 kcal·mol^{-1} and the fluoride–ion affinity is $IA(SF_4) = 59.1\ kcal·mol^{-1}$.

Heat Capacity and Entropy

The infrared and Raman spectra[11,12] of the solid adduct $CsFSF_4$ are consistent with a slightly distorted tetragonal pyramidal structure for the SF_5^- anion. We adopt this configuration assuming the length of the four equivalent bonds is the same as that in SF_6.[7] The axial bond length is taken to be slightly shorter (0.1–) than the equatorial bonds, in accordance with the pattern followed in the related molecules ClF_5[7] and TeF_5^-.[13] The F**–S–F* bond angle has been estimated by Drullinger and Griffiths.[11] The principal moments of inertia are: $I_A = 30.4769 \times 10^{-39}$ and $I_B = I_C = 20.3023 \times 10^{-39}\ g·cm^2$.

Smardzewski and Fox[14] reported the matrix infrared spectra of SF_5^- formed during the vacuum ultraviolet photolysis of $SF_6$and SD_2F_{10} in argon matrices at 8 K. Values of ν_1, ν_3 and ν_7 are taken from this recent study. The other six fundamentals are those measured by Christe *et al.*[12] for the SF_5^- anion observed in the Raman spectra of the solid adduct $CsFSF_4$. An independent set[11] of vibrational frequencies for the SF_5^- anion show good agreement with those adopted here except for ν_8. Drullinger and Griffiths[11] observed a weak band at 388 cm^{-1} in the infrared spectra of solid $Cs^+SF_5^-$ which they assigned to ν_8. This band does not appear in the spectrum reported by Christe *et al.*[12] who assumed a double coincidence between ν_4 and ν_8 as observed for the related molecule ClF_5.[12] We adopt this latter assignment.

Drullinger and Griffiths[11] have previously evaluated thermal functions for SF_5^- at selected temperatures in the range 200–2000 K. Using the bond lengths estimated by Drullinger and Griffiths[11] and their vibrational frequencies, we calculate entropies which are about 0.8 cal $K^{-1}·mol^{-1}$ lower than those reported. The reason for this discrepancy is not apparent.

Ground State Quantum Weight: 1 σ = [6]

Point Group: [C_6]

Bond Distance: F–F = [2.5] Å

Product of the Moments of Inertia: $I_A I_B I_C = [4.833984 \times 10^{-112}]\ g^3 \cdot cm^6$

Enthalpy of Formation

The enthalpy of 6 HF(g) → H_6F_6(g) was taken as the mean of 3rd law values which were determined from the equilibrium data of two investigations. Briegleb and Storhmeier[1] measured the vapor density of associated HF between 20 and 60°C and between 50 and 650 torr. Franck and Meyer[2] measured $C_p°$ between −20 and 100°C and between 100 and 700 torr. Each investigation evaluated K_p at n = 2, 3, 4, ... for the reactions n(HF) → $(HF)_n$ and reported 2nd law values of $\Delta_f H$ and $\Delta_f S$. At n = 6 their 2nd and 3rd law values differed by 0.8 kcal mol^{-1}, which was taken as an estimate of error, while the calculated 3rd law values differed by 0.6 kcal mol^{-1}. Using $\Delta_f H°(298.15\ K) = -41.20$ $kcal \cdot mol^{-1}$ and auxiliary JANAF data[3] gives the enthalpy of formation of H_6F_6(g).

Heat Capacity and Entropy

The molecular structure of H_6F_6 was assumed as planar with the F atoms forming the vertices of a regular hexagon and with the H atoms also lying on the circumscribed circle. That rings are more stable than open chains was confirmed by Del Bene and Pople's[4] theoretical molecular–orbital studies on HF polymers. The length of side (F–F axis) was taken from Atoji and Lipscomb's[5] X–ray studies of solid HF(F–F = 2.49 Å) and agrees with the 2.52 Å which Janzen and Bartell[6] determined for HF gaseous polymers by electron diffraction. The low F–bending frequency (53 cm^{-1}) was taken from Boutin *et al.*[7] The other vibrational frequencies were taken from Kittelberger and Hornig's[8] work on crystalline HF. Huong and Couzi[9] and Smith[10] have made spectral studies of the gas phase in the range from 350 to 4000 cm^{-1}.

The National Bureau of Standards prepared this table[11] by critical analysis of data existing in 1972. Using molecular constants and $\Delta_f H°$ selected by NBS,[11] we recalculate the table in terms of 1973 fundamental constants,[12] 1975 atomic weights,[13] and current JANAF reference states for the elements.

PREVIOUS: June 1977 (1 atm) CURRENT: June 1977 (1 bar)

$S°(298.15\ K) = 259.693 \pm 0.25\ J \cdot K^{-1} \cdot mol^{-1}$
$T_{trs} = 263.5 \pm 0.02\ K$
$T_{fus} = 290.76 \pm 0.02\ K$

$\Delta_f H°(298.15\ K) = -1585.656 \pm 0.11\ kJ \cdot mol^{-1}$
$\Delta_{trs} H° = 8.171 \pm 0.008\ kJ \cdot mol^{-1}$
$\Delta_{fus} H° = 4.326 \pm 0.004\ kJ \cdot mol^{-1}$

Enthalpy of Formation

The adopted $\Delta_f H°(MoF_6, l, 298.15\ K) = -378.98 \pm 0.25\ kcal \cdot mol^{-1} (-1585.657 \pm 0.11\ kJ \cdot mol^{-1})$ is calculated from $\Delta_f H°(MoF_6, g, 298.15\ K) = -372.29 \pm 0.22\ kcal \cdot mol^{-1}$ minus $\Delta_{vap} H°(298.15\ K) = 6.69 \pm 0.03\ kcal \cdot mol^{-1}$ from our 3rd law analysis of vapor pressure data.

The enthalpy of reaction of MoF_6(l) with excess of OH^-(aq) has been measured by Myers and Brady[2] and by Nuttall *et al.*;[3] the derived $\Delta_f H°(MoF_6, l, 298.15\ K)$ is −393.2 and −380.81 ± 1.3-1.0 kcal·mol^{-1}, respectively. The agreement of the latter value with the adopted value is not quite within the assigned uncertainties.

Heat Capacity and Entropy

The heat capacity of MoF_6 has been measured by Brady *et al.* (50–300 K, 4) and by Osborne et al. (4–350 K, 5).

We adopt the more extensive data of Osborne *et al.*[5] extrapolating $C_p°$ linearly with temperature outside the observed range. $S°(298.15\ K) = 62.07 \pm 0.06\ cal\ K^{-1} \cdot mol^{-1}$ is derived from heat capacity, heat of transition, and heat of melting data and $S°(5\ K) = 0.024\ cal\ K^{-1} \cdot mol^{-1}$ from the T^3 extrapolation of Osborne *et al.*[5]

Transition Data

Osborne *et al.*[5] confirmed the solid state transition (263.5 ± 0.02 K, $\Delta_{trs} H° = 1.953 \pm 0.002\ kcal \cdot mol^{-1}$ found by Brady *et al.* (263.6 K, $\Delta_{trs} H° = 1.957 \pm 0.010\ kcal \cdot mol^{-1}$)[4].

Fusion Data

Melting point and enthalpy of fusion data have been reported by several investigators. These results are summarized below:

Source	Method	T_{fus}/K	$\Delta_{fus} H°$, kcal·mol^{-1}
4	Calorimetric	290.7	1.059 ± 0.010
5	Calorimetric	290.76 ± 0.02	1.034 ± 0.001
6	Vap Pressure	290.65	0.858*
7	Vap Pressure	290.55	0.902*
8	Vap Pressure	290.95	0.987*

*Calculated as the difference between the 2nd law heat of sublimation at 291 K and the adopted 3rd law $\Delta_{vap} H°(298.15\ K)$ corrected to 291 K.

We adopt the calorimetric values of Osborne *et al.*[5]

Vaporization Data

Our 2nd and 3rd law analysis of four sets of vapor pressure data produces the following results. The second virial coefficient determined by Osborne *et al.*[5] is used to convert all four vapor pressure data sets to ideal gas fugacity.

Source	T/K	Data Points	$\Delta_{vap} H°(298.15\ K)$, kcal·mol^{-1} 2nd law	3rd law	Drift cal K^{-1}·mol^{-1}
6	291-295	4	5.981 ± 0.467	6.691 ± 0.012	2.42 ± 1.59
7	291-307	Eqn	6.737	6.692 ± 0.002	−0.15
5	291-320	21	6.691 ± 0.002	6.691 ± 0.000	0.00 ± 0.01
8	291-335	Eqn	6.696	6.691 ± 0.001	−0.02

The agreement in 3rd law values is excellent and we adopt $\Delta_{vap} H°(298.15\ K) = 6.69 \pm 0.03\ kcal \cdot mol^{-1}$. $T_{vap} = 308.0\ K$ and $\Delta_{vap} H°(308\ K) = 6.57\ kcal \cdot mol^{-1}$ are calculated for a fugacity of one atmosphere for the process $MoF_6(l) = MoF_6(g)$. For vaporization to the real gas, $T_{vap} = 307.04\ K$ and $\Delta_{vap} H°(307\ K) = 6.51\ kcal \cdot mol^{-1}$.

This table is based on the critical analysis of data existing in 1978 by Brewer.[9]

741.8(1)	264(3)
652.0(2)	317(3)
742 (3)	117(3)

Ground State Quantum Weight: 1 $\sigma = 24$

Point Group: O_h

Bond Distance: Mo–F = 1.82 ± 0.01 Å

Bond Angle: F–Mo–F = 90°

Product of the Moments of Inertia: $I_A I_B I_C = 7.303442 \times 10^{-113}\ g^3 \cdot cm^6$

Enthalpy of Formation

The adopted $\Delta_f H°(MoF_6, g, 298.15\ K) = -372.29 \pm 0.22\ kcal \cdot mol^{-1}$ is from the measurements of the direct combination of the elements by Settle *et al.*[1] with the minor corrections[2] for a change in atomic weights and new values for the enthalpy of formation of MoF_5(cr) and NiF_2(cr).

Burgess *et al.*[3] reacted MoF_6(g) with excess NaOH solution and derived $\Delta_f H°(MoF_6, g, 298.15\ K) = -373.8\ kcal \cdot mol^{-1}$. The result of the direct measurement of Settle *et al.*[1] is preferred. The value of $\Delta_f H°(0\ K)$ combined with JANAF data[15] for Mo(g) and F(g) gives $\Delta_{at} H°(0\ K) = 637.9 \pm 1.5\ kcal \cdot mol^{-1}$ and an average Mo–F bond energy of $\Delta_{at} H°(0\ K)/6 = 106.3 \pm 0.3\ kcal \cdot mol^{-1}$.

Heat Capacity and Entropy

From the Raman spectra of liquid MoF_6, Tanner and Duncan[4] concluded that the structure of the molecule was a regular octahedron with O_h symmetry rather than the unsymmetrical structure deduced by Braune and Pinnow[5] from electron diffraction studies. This discrepancy was explained by Glauber and Schomaker.[6]

Values of the Mo–F bond distance vary from 1.84 Å from electron diffraction[7] to 1.80 Å from x-ray diffraction of the cubic solid.[8] Seip and Seip[9] calculated a bond distance of 1.82 Å from electron diffraction measurements. We adopt this value with an uncertainty of ±0.01 Å.[10] The individual moments of inertia are $I_A = I_B = I_C = 41.8000 \times 10^{-39}\ g \cdot cm^2$.

The vibrational frequencies are those adopted by Brewer[10] from the assignment by Weinstock and Goodman[11] and the more recent studies of Claasen *et al.*[12] and McDowell *et al.*[13]

$S°(MoF_6, g, 298.15\ K) = 83.796\ cal\ K^{-1} \cdot mol^{-1}$ calculated from the molecular data is in excellent agreement with $S°(MoF_6, l, 298.15\ K) = 62.068\ cal\ K^{-1} \cdot mol^{-1}$ plus $\Delta_{vap} S°(298.15\ K) = 21.727\ cal\ K^{-1} \cdot mol^{-1}$ to give $S°(MoF_6, g, 298.15\ K) = 83.795 \pm 0.10\ cal\ K^{-1} \cdot mol^{-1}$ based on our analysis of the data of Osborne *et al.*[14]

This table is based on the critical analysis of data existing in 1978 by Brewer.[10]

Bond Angle: F–S–F = 90°

Product of the Moments of Inertia: $I_A I_B I_C = 2.941168 \times 10^{-113}\ g^3 \cdot cm^6$

Enthalpy of Formation

The calorimetric measurement of $\Delta_f H°$ by direct combination of the elements has been the subject of numerous investigations.[1–6] O'Hare *et al.*[1] performed six combustion experiments on a sample of rhombic sulfur which contained 60 ppm oxygen as the major impurity. The sulfur (−0.5 gram) was burned in 5–6 atmospheres of fluorine which had a purity of 99.97%. Spectrometric and gas chromatographic analyses of the product gases indicated that the sole combustion product was SF_6. We adjust their result $\Delta_f H°(298.15\ k) = -271.7 \pm 0.24\ kcal \cdot mol^{-1}$ to correspond to an atomic weight of sulfur equal to 32.06, and we obtain $\Delta_f H°(SF_6, g, 298.15\ k) = -291.7_3 \pm 0.2\ kcal \cdot mol^{-1}$. The rounded value of $-291.7 \pm 0.2\ kcal \cdot mol^{-1}$ is adopted in this tabulation. Less extensive measurements (3 determinations) by Schroder and Sieben[2] on a portion of the same sample used by O'Hare *et al.*[1] gave $\Delta_f H°(SF_6, g, 298.15\ K) = -291.4\ kcal \cdot mol^{-1}$ which provides confirmation for our selected value.

Other reported $\Delta_f H°$ values which are consistently less negative than the value selected here include (in $kcal \cdot mol^{-1}$) -291.0 ± 0.3,[3] -288.9 ± 0.7,[4] -288.5 ± 0.7[5] and -262.0.[6] The fluorine used by Leonidov *et al.*[3] contained 0.13 wt. % oxygen, and this impurity may be responsible for their low results. Gross *et al.*[4] studied the sulfur fluorination reaction in a glass apparatus and also applied their technique to titanium. Their reported $\Delta_f H°$ value for TiF_4 is in satisfactory agreement ($\pm 0.8\ kcal \cdot mol^{-1}$) with JANAF data.[7] Insufficient information has been reported[4] to resolve the discrepancy for SF_6.

Our adopted $\Delta_f H°$ value is essentially the same as that recently selected by NBS.[8] The earlier NBS selection[9] of $-289.0\ kcal \cdot mol^{-1}$ based on the work of Gross *et al.*,[4,5] is unreliable.

Heat Capacity and Entropy

The product of the moments of inertia is calculated for a structure in which the fluorine atoms lie at the corners of a regular octahedran. This structure belongs to the highest symmetry point group O_h ($\sigma = 24$) and is consistent with observations made from electron diffraction,[10–12] Raman[13–15] and infrared[16–18] studies. The bond length and angle are from the electron diffraction work of Ewing and Sutton.[10] Earlier and less precise work[11–12] led to r_e(S–F) values which are only slightly different from the adopted value. The individual moments of inertia are: $I_A = I_B = I_C = 30.8679 \times 10^{-39}\ g \cdot cm^2$.

The SF_6 molecule has been extensively characterized by vibrational spectroscopy. Weinstock and Goodman[19] reviewed work prior to 1965. Recent studies include gas–phase Raman,[13–14] matrix–isolation Raman,[15] and gas–phase infrared.[16–18] These spectrometric results are in good agreement; the largest deviation arising in the Raman and infrared inactive fundamental ν_6. Weinstock and Goodman[19] obtained $\nu_6 = 349\ cm^{-1}$ from the combination (2 + 6) band. Claassen *et al.*[13] reported $\nu_6 = 347\ cm^{-1}$ from the overtone $2\nu_6$ band, and Holzer and Ouillon[14] have directly observed this forbidden fundamental in the collision–induced Raman spectra at 336 cm^{-1}. Rosenberg and Birnbaum[20] recorded the far–infrared absorption spectrum of gaseous SF_6 and assigned a band centered at 173 cm^{-1} to $\nu_5 - \nu_6$. The difference band gives $\nu_6 = 352\ cm^{-1}$ with $\nu_5 = 525\ cm^{-1}$ [13] and supports the higher value for ν_6. All frequencies used in this tabulation except for the two infrared active (ν_3 and ν_4) fundamentals are taken from the work of Claassen *et al.*[13] Values for the infrared active frequencies are from Abramowitz and Levin.[16] Recent MO calculations[21] predict a singlet ground state with no low–lying electronic levels, and are supported by the x–ray emission[22] and absorption[22,23] spectra of gaseous SF_6. Gianturco[28] has presented a description of the electronic properties.

Kelley and King[24] analyzed $C_p°$ data (13–230 K) reported by Eucken and Schroder[25] and obtained $S°(298.15\ K) = 70.3 \pm 0.7\ cal\ K^{-1} \cdot mol^{-1}$ for the gas phase. This value is in reasonable agreement with the spectroscopic result ($69.7 \pm 0.1\ cal\ K^{-1} \cdot mol^{-1}$). Our thermal functions essentially extend and update those reported in the literature.[1,26,27]

Enthalpy of Formation

We calculate the enthalpy of formation at 0 K as the difference between $\Delta_f H°(SF_6, g) = -288.36 \pm 0.2$ kcal·mol^{-1} [1] and the selected value of the electron affinity (EA) equal to 1.2 ± 0.3 eV (27.67 kcal·mol^{-1}). There have been numerous values proposed for EA(SF_6). Franklin and Harland[2] have recently reviewed several of the published values; other values of EA not included in the review are tabulated below. The only direct measurement of EA = 1.49 eV by the magnetron technique[3] is suspect since mass spectral studies[4] have shown that SF_5 rather than SF_6 is the predominant ion formed under conditions used in the magnetron experiments. An EA = 1.2 eV is consistent with most of the available information and is adopted here as the best current value.

Source	Method	EA(SF_6), eV
[5]	Electron Transfer	<1.18
[6]	Collisional Ionization Cs/SF_6	>0.54
[7]	Rate Measurements	>0.7
[8]	Electron Transfer	>0.43
		<1.47
[9]	Solution Electron Transfer	0.6
[10]	MO Calculation	1.7

From the adopted results, we calculate the primary bond dissociation energy $D_0°(SF_6^- - F)$ to be 34.4 kcal·mol^{-1} which agrees with the value of 24.2 kcal·mol^{-1} obtained from threshold energies for SF_6^- and SF_5^- measured in collisional ionization studies[6] on the Cs/SF_6 system. $\Delta_f H°(298.15\ K)$ is −320.7 kcal·mol^{-1}, and the fluoride ion affinity (IA) is IA = 41.3 kcal·mol^{-1}.

Heat Capacity and Entropy

The six fluorine atoms are assumed to form a regular octahedron around the central sulfur atom, in accordance with observations[11] on the ESR spectrum of SF_6^-. The value of the bond length is taken from theoretical calculations.[11] This value (1.72 Å) is intermediate between the bond lengths for SF_6[1] and XeF_6[12] and therefore appears to be a reasonable estimate. The principal moments of inertia are: $I_A = I_B = I_C = 37.3328 \times 10^{-39}\ g \cdot cm^2$.

MO calculations[11] in the INDO approximation indicate that the unpaired electron occupies a totally symmetric antibonding orbital (A_{1g}). Thus, we predict that the bonding in SF_6^- is somewhat weaker than that in the neutral molecule. Additional support for this is provided by the fact that the mean S–F bond energy (products S(g)+F (g) + 5F(g)) in SF_6^- is 8.5 kcal·mol^{-1} less than that in SF_6.[1] Due to the weaker bonding in SF_6^-, all vibrational frequencies are expected to show a lowering relative to those for SF_6.[1] Very recently, Barefield and Guillory[13] have assigned an absorption band at 594 cm^{-1} observed in the matrix isolated infrared spectra of NO, Na, and K photoionized in the presence of SF_6 as the ν_4 fundamental of SF_6^-. This represents a lowering of 21.3 cm^{-1} from the gas phase frequency for SF_6.[1] The other infrared active mode (ν_3) for SF_6^- expected to lie near 925 cm^{-1} was not observed but was believed to be hidden beneath the matrix isolated ν_3 band (937 cm^{-1}) of SF_6. We estimate the eight unobserved fundamental from the gas phase values for SF_6.[1]

MO calculations[11] indicate that the ground state electronic configuration is A_{1g}. There is, however, little information available on the excited states for SF_6^- or for isoelectronic molecules such as $ClF_6$6 and BrF_6. Indirect experimental evidence for the existence of an excited state at 0.5 eV (4033 cm^{-1}) has been reported by Lifshitz *et al.*[14] from mass spectral studies of charge–transfer reactions. As shown by Fehsenfeld,[15] stable excited states are expected to exist only if $D_0°(SF_5 - F) > EA(SF_6)$. Our adopted results give a difference in $D_0°(SF_5 - F)$ and EA(SF_6) of only 0.053 eV, suggesting that perhaps the SF_6^- ion observed by Lifshitz *et al.*[14] was vibrationally rather than electronically excited. We prefer not to include this level, but if it does exist, our entropies should be increased by 0.41 and 1.0 cal $K^{-1} \cdot mol^{-1}$ at 2000 K and 4500 K.

PREVIOUS: June 1977 (1 atm) CURRENT: June 1977 (1 bar)

$S°(298.15\ K) = 249.216 \pm 0.8\ J \cdot K^{-1} \cdot mol^{-1}$
$T_{fus} = 275.2\ K$

$\Delta_f H°(298.15\ K) = -1748.368 \pm 2.1\ kJ \cdot mol^{-1}$
$\Delta_{fus} H° = 4.100\ kJ \cdot mol^{-1}$

Enthalpy of Formation

The adopted enthalpy of formation, $-417.87\ kcal \cdot mol^{-1}$, is calculated from the chosen $\Delta_{vap}H°(290.3\ K) = 6.465 \pm 0.08\ kcal \cdot mol^{-1}$ with $\Delta_f H°(WF_6, g, 298.15\ K) = -411.5 \pm 0.4\ kcal \cdot mol^{-1}$. The value of $\Delta_{vap}H°(290.3\ K)$ is obtained by corrected 2nd law analysis of vapor pressure data[6,7,8] which are given in the vaporization section of this table.

Myers and Brady[1] measured calorimetrically $\Delta_r H°(298.15\ K) = -150.1\ kcal \cdot mol^{-1}$ for the reaction $WF_6(l) + 8\ NaOH(aq, 500\ H_2O) \rightarrow Na_2WO_4(aq, 4900\ H_2O) + 4\ H_2O(l) + 6\ NaF(aq, 800\ H_2O)$. Spitsyn and Patsukova[2] measurd calorimetrically $\Delta_r H°(298.15\ K) = -13.8\ kcal \cdot mol^{-1}$ for the reaction $WO_3(cr) + 2\ NaOH_4(aq, 66\ H_2O) \rightarrow Na_2WO_4(aq, 4200\ H_2O) + H_2O(l)$. Based on these data and auxiliary data for NaOH(aq),[3,9] NaF(aq)[3,10] and $Na_2WO_4(aq)$[4] we obtain $\Delta_r H°(298.15\ K) = -136.2\ kcal \cdot mol^{-1}$ for $WF_6(l) + 6\ NaOH(aq, \infty) \rightarrow WO_3(cr) + 3\ H_2O(l) + 6\ NaF(aq, \infty)$. This leads to $\Delta_f H°(WF_6, l, 298.15\ K) = -416.9 \pm 1\ kcal \cdot mol^{-1}$ which is in good agreement with the value adopted.

Heat Capacity and Entropy

The heat capacity, $40.5\ cal\ K^{-1} \cdot mol^{-1}$, is obtained from a graph of the $C_p°$ versus temperature curve determined calorimetrically by Westrum.[5]

The entropy, $S°(298.15\ K) = 59.564\ cal\ K^{-1} \cdot mol^{-1}$, is calculated from the chosen $\Delta_{vap}H°(290.3) = 6.465\ kcal \cdot mol^{-1}$ with $S°(WF_6, g, 298.15\ K) = 81.50\ cal\ K^{-1} \cdot mol^{-1}$.

Fusion Data

The melting point and heat of melting have been reported by the following investigators, and their results are summarized below. Ruff and Ascher's value, $2.40\ kcal \cdot mol^{-1}$, is too high because they did not know of the existence of a solid–solid transition[5] at 264.7 K with $\Delta_{trs}H° = 2.067\ kcal \cdot mol^{-1}$. Westrum's data are adopted in the tabulation.

Source	Method	T_{fus}/K	$\Delta_{fus}H°\ kcal \cdot mol^{-1}$
5	Calorimetric	275.2	0.980
7	Vapor pressure	275.4	2.400*
8	Warming curve	275.1	0.500
6	Vapor pressure	275.2	0.420*

*This value is the difference between the 2nd law heats of sublimation and vaporization without correction for $\Delta C_p°$ for both processes.

Vaporization Data

2nd law analyses of the data,[6,7,8] neglecting corrections for nonideality of the vapor, are summarized below. The value of $\Delta_{vap}H°(298.15\ K) = 6.37\ kcal \cdot mol^{-1}$ ($\Delta_{vap}H°(290.3\ K) = 6.465\ kcal \cdot mol^{-1}$ is selected in the tabulation.

Enthalpy of Formation

O'Hare and Hubbard[7] determined the enthalpy of formation, $\Delta_f H°(WF_6, g, 298.15\ K) = -411.5 \pm 0.4\ kcal·mol^{-1}$, by combustion of tungsten in fluorine in a bomb calorimeter. This value is adopted in the tabulation.

Heat Capacity and Entropy

The molecular configuration and vibrational frequencies were obtained from the infrared and Raman spectroscopic studies by Gaunt,[1] Burke *et al.*[2] and Tanner and Duncan.[3]

The bond distance was reported by Claasen,[4] based on the preliminary result of Schomaker *et al.*[5] who determined the bond distance by electron diffraction. Gaunt[6] derived W–F = 1.89 Å from correlations with other hexafluorides and a valence force constant calculation. The three principal moments of inertia are $I_A = I_B = I_C = 42.2606 \times 10^{-39}\ g·cm^2$.

Ground State Quantum Weight: 1 σ = [7]
Point Group: [C_7]
Interatomic Distance: F–F = [2.5]Å
Product of the Moments of Inertia: $I_A I_B I_C$ = [1.797733 × 10^{-111}] $g^3·cm^6$

Enthalpy of Formation

The enthalpy of 7 HF(g) → H_7F_7(g) was taken as the mean of 3rd law values which were determined from the equilibrium data of two investigations. Briegleb and Strohmeier[1] measured the vapor density of associated HF between 20 and 60°C and between 50 and 650 torr. Franck and Meyer[2] measured $C_p°$ between −20 and 100°C and between 100 and 700 torr. Each investigation evaluated K_p at n = 2, 3, 4, ... for the reactions n(HF) → (HF) and reported 2nd law values of ΔH and ΔS. At n = 7 their 2nd law values differed by 7.3 $kcal·mol^{-1}$, which was taken as an estimate of error, while the calculated 3rd law values differed by 6.4 $kcal·mol^{-1}$. Using $\Delta_f H°(298.15\ K)$ = 046.54 $kcal·mol^{-1}$ and auxiliary JANAF data[3] gives the enthalpy of formation of H_7F_7(g).

Heat Capacity and Entropy

The molecular structure of H_7F_7 was assumed as planar with the F atoms forming the vertices of a regular heptagon and the H atoms also lying on the circumscribed circle. That rings are more stable than open chains was confirmed by Del Bene and Pople's[4] theoretical molecular orbital studies on HF polymers. The length of side (F–F axis) was taken from Atoji and Lipscomb's[5] X-ray studies of solid HF (F–F = 2.49 Å) and agrees with the 2.52 Å which Janzen and Bartell[6] determined for HF gaseous polymers by electron diffraction. The low F bending frequency (53 cm^{-1}) was taken from Boutin *et al.*[7] The other vibrational frequencies were taken from Kittelberger and Hornig's[8] work on crystalline HF. Huong and Couzi[9] and Smith[10] have made spectral studies of the gas phase in the range from 350 to 4000 cm^{-1}.

The National Bureau of Standards prepared this table[11] by critical analysis of data existing in 1972. Using molecular constants and $\Delta_f H°$ selected by NBS,[11] we recalculate the table in terms of 1973 fundamental constants,[12] 1975 atomic weights[13] and current JANAF reference states for the elements.

Ground State Quantum Weight: [1] $\sigma = 10$

Point Group: D_{5h}

Bond Distances: I–F(equatorial) = 1.86 Å; I–F(axial) = 1.76 Å

Bond Angles: F(eq)–I–F(ax) = 90°; F(eq)–I–F(eq) = 72°

Product of the Moments of Inertia: $I_A I_B I_C = 1.196821 \times 10^{-112}\ g^3 \cdot cm^6$

Enthalpy of Formation

Settle *et al.*[1] derived $\Delta_f H° = 229.7 \pm 0.6$ kcal·mol^{-1} for IF_7(g) at 298.15 K from treatment of their calorimetric data on combustion of iodine in fluorine. The combustion products, consisting of mixtures of IF_5 and IF_7, were expanded, treated to remove excess fluorine, and then hydrolyzed. The solutions were analyzed for iodate and the sum of iodate plus periodate. Since the recovery of iodine was not complete (about 70 to 99%), it was necessary to try various assumptions about the form of the unrecovered iodine. Consistent results were obtained only by assigning the unrecovered iodine to IF_7, the less volatile product. This treatment indicated that IF_7 was formed in yields ranging from about 1 to 70%.

$\Delta_r H°$ for the reaction $IF_7(g) \rightarrow IF_5(g) + F_2(g)$ may be checked via equilibrium data.[2] Using six points read from Figure 2 of Bernstein and Katz, we obtain $\Delta_r H°$(3rd law) = 29.36 ± 0.2 kcal·mol^{-1} and $\Delta_r H°$(2nd law) = 29.53 ± 0.7 kcal·mol^{-1}, both at 298.15 K. The entopy test, $\Delta_r S°$(2nd law) $\Delta_r S°$(JANAF Functions) = 0.3 ± 1.4 cal K^{-1}·mol^{-1}, indicates consistency with the JANAF functions. Combination of $\Delta_r H°$(3rd law) with $\Delta_f H°$ for IF_5(g) yields $\Delta_f H°(IF_7, g) = -230.2 \pm 0.6$ kcal·mol^{-1}. In deriving the uncertainty, we assume that $\Delta_r H°$(3rd law) is uncertain by ±0.5 kcal·mol^{-1} due to an estimated uncertainty of about 1.0 cal K^{-1}·mol^{-1} in the JANAF value of $\Delta_r S°$ at 500 K.

Heat Capacity and Entropy

Recent evidence favors D_{5h} symmetry and a pentagonal bipyramidal structure for the heptafluoride. Claassen *et al.*[3] review the earlier debate about structure of lower symmetry. They provide convincing evidence of D_{5h} symmetry from the first observation of Raman spectra of the vapor state and re examination of the infrared spectra. Their data including five fundamentals in Raman (two polarized), five fundamentals in infrared, no coincidences between Raman and infrared, and one fundamental inactive are consistent only with D_{5h} symmetry. This is confirmed by Falconer *et al.*[4] who interpret their electric deflection experiments as indicating a symmetry forbidden dipole moment. Extended Huckel molecular orbital calculations[5] also predict D_{5h} symmetry. The adopted structural parameters are from our approximate analysis of the electron diffraction data of Thompson and Bartell.[6] The authors gave a radial distribution curve and suggested only a gross (unrefined) structure because of the probable presence of a fluorocarbon impurity in their sample. Principal moments of inertia are $I_A = I_B = 46.8306 \times 10^{-39}$ and $I_C = 54.5719 \times 10^{-39}$ g·cm^2.

Observed vibrational fundamentals are from Claassen *et al.*[3] The inactive fundamental is estimated from the calculations of Khanna.[7]

Enthalpy of Formation

We adopt $\Delta_f H°(298.15\ K) = -644.8 \pm 2\ kcal \cdot mol^{-1}$ in agreement with Brewer.[1] This is derived by proceeding from $\Delta_f H°(MoF_5, cr, 298.15\ K)$ to $\Delta_f H°(MoF_5, l, 298.15\ K)$ to $\Delta_f H°$(dimer, g, 298.15 K). Brewer[1] adopted $\Delta_f H°(MoF_5, cr, 298.15\ K) = -331.9 \pm 1\ kcal \cdot mol^{-1}$ from the measurements of Burgess *et al.*[2a]nd Nuttall *et al.*[3] Krause and Douglas[4] measured $\Delta_{fus}H°(318.82\ K) = 1.46 \pm 0.07\ kcal \cdot mol^{-1}$ and the $\Delta C_p°$ correction to 298.15 K is only $-4\ cal\ K^{-1} \cdot mol^{-1}$. The heat of vaporization to the dimer $\Delta_{vap}H°(298.15\ K) = 15.99\ kcal \cdot mol^{-1}$ was derived by Krause[5] from vapor density data.

The value of $\Delta_f H°(0\ K)$ combined with JANAF data[11] for Mo(g) and F(g) gives $\Delta_{at}H°(0\ K) = 1139.9 \pm 8\ kcal \cdot mol^{-1}$ and an average bond energy of $\Delta_{at}H°(0\ K)/10 = 114.0 \pm 1\ kcal \cdot mol^{-1}$.

Heat Capacity and Entropy

For Mo_2F_{10}(g), the dimer of MoF_5(g), Douglas,[6] Krause,[5] and Brewer[1] have used the MoF_5(g) frequencies with doubled degeneracy along with estimates of two triply degenerate frequencies. The frequencies, cm^{-1}, and degeneracies for MoF_5(g) were assigned from the spectroscopic data of Acquista and Abramowitz[7] and two fundamentals were estimated[8] -- 759(1), 738(1), 683(1), [500](1), 713(2), 261(2), ll2(2), and [200](2). Douglas[6] and Krause[5] elected to use an estimate of [400](2) rather than [200](2) while, for MoF_5, Brewer[1a]nd Hildenbrand[9] retained the [200](2) estimate. The derived functions for Mo_2F_{10}(g) presented here and by Brewer[1] use the [400](4) estimate. For the six remaining frequencies, Douglas[6] has chosen the estimates [121](3) and [90](3) and Krause[5] has chosen [60](6); Brewer[1] has used [90](3) and [60](3), one of the alternative estimates of Douglas,[6] in order to match the selected entropy of the liquid and the entropy of vaporization to the dimer.[5] We adopt Brewer's[1] evaluation of the vibrational assignment and the estimate of an electronic ground state quantum weight of [3].[1-6]

By analogy with the MoF_5(cr) structure,[10] the dimer(g) molecule was assumed to have the structure of two octahedra sharing a common edge.[5, 6] The two Mo atoms at the centers of the octahedra and the two bridging F atoms at the ends of the common edge form Mo–F–Mo angles of 90°. The bridging Mo–F bond distance of 2.06 Å and the non bridging Mo–F distance of 1.78 Å from MoF_5(cr),[10] were assumed for the gaseous dimer. All adjacent F–Mo–F angles are 90°.

The principal moments of inertia are: $I_A = 73.3619 \times 10^{-39}$, $I_B = 220.8005 \times 10^{-39}$, $I_C = 227.4042 \times 10^{-39}\ g \cdot cm^2$.

This table is in good agreement with the critical evaluation by Brewer[1] on which it is based.

Barrier to Internal Rotation: V = [8.0] $kcal \cdot mol^{-1}$

Enthalpy of Formation

The kinetics of the decomposition of gaseous S_2F_{10} have been studied by Trost and McIntosh[1] from 434 455 K. Benson and Bott[2] have reevaluated these kinetic data and have reported two values for the equilibrium constant of the dissociation process $S_2F_{10}(g) = SF_4(g) + SF_6(g)$. Both values refer to a temperature of 444 K. We analyze these two K_p values by the 3rd law method, and we obtain the result $\Delta_r H°(298.15\ K) = 19.26 \pm 1.4\ kcal \cdot mol^{-1}$. The adopted value of $\Delta_f H°(S_2F_{10}, g, 298.15\ K) = -493.4 \pm 7\ kcal \cdot mol^{-1}$ is obtained by combining the value of $\Delta_r H°$ with JANAF enthalpies of formation[3] for SF_4 and SF_6.

The heat of atomization, $\Delta_{at} H°(0\ K)$, and bond dissocation energy $D_0°(F_5S–SF_5)$ are calculated to be $802.8 \pm 11.0\ kcal \cdot mol^{-1}$ and $58.4 \pm 14.0\ kcal \cdot mol^{-1}$, respectively. The latter value agrees with an upper limit value of $62.6\ kcal \cdot mol^{-1}$ for the bond energy of a covalent S–S linkage established from thermochemical data[3] for the S_8 ring.

Heat Capacity and Entropy

The results of electron diffraction experiments[4] show that the S_2F_{10} molecule consists of two SF_5 octahedral groups sharing a common S–S bond. The adopted bond lengths and angles are taken from this study.[4] The relative orientation of the two SF_5 groups has not been experimentally established,[5–7] but the staggered configuration of D_{4d} symmetry has been predicted to be more stable[8] than the eclipsed form (D_{4h} symmetry). We assume that the point group is D_{4d}. The principal moments of inertia are: $I_A = 61.4204 \times 10^{-39}$ and $I_B = I_C = 119.3402 \times 10^{-39}\ g \cdot cm^2$.

The vibrational spectra of S_2F_{10} have been studied in detail in three independent investigations.[5–7] The reported fundamental frequencies show reasonable agreement but the assignments of the observed fundamentals made by Wilmshurst and Bernstein[5] differ somewhat from those made by Dodd *et al.*[6] The adopted frequencies and assignments except for the torsion (ν_5) and SF_5 rocking frequency (ν_{12}) are taken from Dodd *et al.*[6] We estimate the unobserved ν_{12} fundamental at 150 cm^{-1}. Other estimated values that have been reported include 200 cm^{-1} [2] and 37 cm^{-1}.[5] The inactive torsional frequency is treated as a hindered internal rotation. We use an estimated potential barrier of 8.0 $kcal \cdot mol^{-1}$ [5] to calculate heat capacity contributions for hindered rotation from the table of Pitzer and Brewer.[9] Contributions below 201 K could not be obtained by this procedure since the values of the ratio V/RT were outside the range of the table. $C_p°$ value between 150 200 K are estimated by graphical interpolation of the hindered rotor $C_p°$ data above 210 K and the corresponding data for a harmonic oscillator ($\nu_5 = 89$ cm^{-1})[5] below 150 K. This treatment assumes that the internal rotation approaches harmonic oscillation as V/RT >> 1. The uncertainty (±2 cal $K^{-1} \cdot mol^{-1}$) in the value of $S°(298.15\ K)$ includes the possibility that the potential barrier is as low as 4.0 $kcal \cdot mol^{-1}$ [8] and contains a contribution from the uncertainty due to the two estimated vibrational frequencies.

Previously published thermodynamic functions[10,11] for S_2F_{10} are based on the assumption that free internal rotation exists in the molecule and on different estimates[5] for the SF_5 rocking fundamentals. Benson and Bott[2] have shown that these earlier frequencies[5] give values for $S°(S_2F_{10}, g)$ which are too high by several units. Our treatment of internal rotation is consistent with the interpretation of electron diffraction data[4] which indicates that the rotation is not completely restricted. It should also be noted that the $C_p°$ data reported by Pass[11] are erroneous above 400 K.

683 (3)	[400](6)
[500](3)	[106](6)
713 (6)	[53](6)

Ground State Quantum Weight: [4] σ = [6]

Point Group: $[D_{3h}]$

Bond Distances: Mo–F = [1.78] Å; $Mo–F_{bridge}$ = [2.06] Å

Bond Angles: F–Mo–F = [90° or 180°]; $F_{bridge}–Mo–F_{bridge}$ = [90°]

Product of the Moments of Inertia: $I_A I_B I_C = [9.5696 \times 10^{-110}]\ g^3 \cdot cm^6$

Enthalpy of Formation

We adopt $\Delta_f H°(Mo_3F_{15}, g, 298.15\ K) = -971.7 \pm 5\ kcal \cdot mol^{-1}$ to agree with Brewer.[1] This is based on 1) the $\Delta_f H°(MoF_5, cr, 298.15\ K) = -331.9 \pm 1\ kcal \cdot mol^{-1}$ adopted by Brewer from the measurements of Burgess *et al.*[2] and Nuttall *et al.*[3] 2) the heat of fusion $\Delta_{fus}H°(318.82\ K) = 1.46 \pm 0.07\ kcal \cdot mol^{-1}$ measured by Krause and Douglas,[4] and 3) a heat of vaporization to the trimer $\Delta_{vap}H°(298.15\ K) = 18.9\ kcal \cdot mol^{-1}$. This heat of vaporization was derived by Brewer[1] from a re-evaluation of the vapor density data of Douglas[5] — the proportion of $Mo_3F_{15}(g)$ in the saturated vapor was reduced to be consistent with no appreciable monomer and a vapor density corresponding to $Mo_2F_{10}(g)$. Douglas[5] had chosen $\Delta_{vap}H°(298.15\ K)$ of $MoF_5(l)$ to $Mo_3F_{15}(g)$ equal to 17.7 $kcal \cdot mol^{-1}$ from a possible range of 16 to 21 $kcal \cdot mol^{-1}$. The value of $\Delta_f H°(0\ K)$ combined with JANAF data[6] for Mo(g) and F(g) gives $\Delta_{at}H°(0\ K) = 1714.5 \pm 14\ kcal \cdot mol^{-1}$ and an average Mo–F bond energy of $\Delta_{at}H°(0\ K)/15 = 114.3 \pm 1\ kcal \cdot mol^{-1}$.

Heat Capacity and Entropy

Brewer[1] has followed Douglas's[5] choice of [4] for the electronic ground state quantum weight, 2) of vibrational frequencies and 3) of molecular configuration.

The $MoF_5(g)$ monomer vibrational frequencies were used, with triple the degeneracy, for the trimer, Mo_3F_{15}, and the 12 remaining frequencies were estimated as [106](6) and [53](6).[5] The vibrational frequencies for $MoF_5(g)$ had been assigned from the spectroscopic data of Aquista and Abramowitz[7] and two fundamentals had been estimated;[8] these frequencies, cm^{-1}, and degeneracies are 759(1), 738(1), 683(1), [500](1), 713(2), 261(2), and [200](2). Douglas[5] used [400](2) rather than [200](2).

The structure assumed by Douglas[5] consists of three tetragonal bipyramids joined by three bridging F atoms such that the three Mo atoms and the three bridging F atoms form a planar, irregular hexagon. The $F_{bridge}–Mo–F_{bridge}$ angles are 90°, the Mo– F_{bridge}–Mo angles are 150°; the remaining F–Mo–F angles are either 90° or 180°. The Mo–F_{bridge} bond distance, 2.06 Å, and the Mo–F bond distance, 1.78 Å, are taken from the x-ray study of MoF_5(cr) by Edwards *et al.*[9]

The principal moments of inertia are $I_A = I_B = 3.8417 \times 10^{-37}$, $I_C = 6.4840 \times 10^{-37}\ g \cdot cm^2$.

This table is in good agreement with the critical evaluation of Brewer[1] on which it is based.

However, thermodynamic functions calculated with the alternate set of vibrational constants are not significantly different from those adopted here. The uncertainty in the $\omega_e x_e$ values is large, probably near ± 1 cm^{-1}. The partition function $Q = Q_t \Sigma Q_r^i Q_v^i g_i \exp(-C_2\epsilon_i/T)$ is used to calculate the thermodynamic functions with first-order anharmonic corrections included for Q_r and Q_v.

is 158°. An energy minimum has been reported at 140° with a CNDO approximation.[19] Unfortunately, the vapor pressure data are not sufficiently precise to be of use in the selection of a structure. The entropies of these two forms differ by only about 1.5 cal $K^{-1}\cdot mol^{-1}$ at temperatures in the range of the vapor pressure data. We tentatively adopt a bond angle of 158° but assign an alternate uncertainty (± 3 cal $K^{-1}\cdot mol^{-1}$) to $S°(298.15\ K)$ to include the possibility that the angle is 180°. The Mg–F bond length is taken from the electron diffraction studies of Akishin *et al.*[11] The individual moments of inertia are: $I_A = 0.2808 \times 10^{-39}$, $I_B = 19.0477 \times 10^{-39}$, and $I_C = 9.3285\ 10^{-39}$ g·cm^2.

The symmetric stretching frequency is a compromise between the Krypton matrix infrared ($\nu_1 = 478$ cm^{-1})[17] and Raman ($\nu_1 = 545$ cm^{-1})[23] values. Also, an intermediate value ($\nu_2 = 215$ cm^{-1}) is selected for the bending frequency from the estimated gas–phase value (270 cm^{-1}) of Snelson[13] and that (165 cm^{-1}) which was observed in the high temperature (~2000 K) infrared spectrum[20] of the vapor. ν_3 is the gas phase value that was estimated by Snelson[13] from frequencies measured in three matrices. The Krypton frequencies for ν_2 and ν_3 reported by Mann *et al.*[17] and Lesiecki and Nibler[23] agree quite well with those of Snelson.[13] Also, the results of Hauge *et al.*[22] provide further support for the adopted ν_3 value. If MgF_2 is assumed to be linear and ν_2 is reduced to 165 cm^{-1}, then our free energy functions are decreased by 2.1 cal $K^{-1}\cdot mol^{-1}$ at 298.15 K, 1.6 cal $K^{-1}\cdot mol^{-1}$ at 1000 K and 1.0 cal $K^{-1}\cdot mol^{-1}$ at 2000 K. These alternate functions are also reasonably consistent with the reported vapor pressure data. Previously published free energy functions[21] for MgF_2(g) which were based on a linear structure are several units (2 5 cal $K^{-1}\cdot mol^{-1}$) too low due to the use of an incorrect bending frequency (470 cm^{-1}).

$S°$(298.15 K) = 57.588 ± 0.42 J·K^{-1}·mol^{-1}
T_{fus} = 1650 K

$\Delta_f H°$(0 K) = −267.123 ± 0.84 kJ·mol^{-1}
$\Delta_f H°$(298.15 K) = −266.270 ± 0.84 kJ·mol^{-1}
$\Delta_{fus} H°$ = 31.338 kJ·mol^{-1}

Enthalpy of Formation

The chemical equilibria in the Fe–C–O and Fe–H–O system have been studied by many investigators. Using the reported equilibrium constants for the following two reactions (A) $Fe_{0.947}O$(cr) + CO(g) = 0.947Fe(cr) + CO_2(g) and (B) $Fe_{0.947}O$(cr, l) + H_2(g) = 0.947Fe(cr) + H_2O(g), the corresponding enthalpy changes $\Delta_r H°$ were evaluated by both the 2nd and 3rd law methods. Based on the 3rd law values for $\Delta_r H°$, the $\Delta_f H°$(Wustite, cr, 298.15 K) values were also calculated. The results obtained are presented as follows.

Source	Reaction	T/K	$\Delta_r H°$(298.15 K), kcal·mol^{-1} 2nd law	3rd law	$\Delta_f H°$(298.15 K) kcal·mol^{-1}
Eastman[1]	A	873.2–1273.2	−3.80 ± 0.01	−4.01	−63.63

Chipman–Marshall[6]	B	1438.2–1633.2	5.03 ± 0.34	5.85	−62.83
Chipman–Marshall[6]	B	1653.2–1787.2	−2.61 ± 0.77	−0.02	−61.87
Jominy–Murphy[5]	B	1698.0–1700.0	−0.87	−62.72	
Britzke *et al.*[4]	C	1123.0 1473.0	−129.08 ± 0.18	−126.28	−63.14

Britzke *et al.*[4] also determined the equilibrium pressures for the reaction (C) 1.894 Fe(cr) + O_2(g) = 2$Fe_{0.947}O$(cr). The corresponding $\Delta_f H°$(298.15 K) for Wustite was evaluated based on the 3rd law value for $\Delta_r H°$(298.15 K). The adopted value of $\Delta_f H°$(Wustite, cr, 298.15 K) is the weighted average of the $\Delta_f H°$(298.15 K) listed in the above table.

Heat Capacity and Entropy

The low temperature (54.37–298.16 K) heat capacities were measured by Todd and Bonnickson.[7] The high temperture (298–1650 K) heat capacities were determined by Coughlin *et al.*[8] The two sets of $C_p°$ data were plotted and joined smoothly at 298.15 K. The $C_p°$ values above 1650 K were obtained by graphical extrapolation. The low temperature (70.7–279.8 K) $C_p°$'s were also reported by Millar.[9] $S°$(298.15 K) was derived from the low-temperature heat capacities, based on $S°$(52 K) = 0.696 cal·K^{-1}·mol^{-1}. Todd and Bonnickson[7] added 0.41 cal·K^{-1}·mol^{-1}, the amount calculated for completely random distribution of the vacant Fe spaces in the Wustite lattice. However, the Gibbs energy functions derived from $S°$(52 K) = 0.696 cal·K^{-1}·mol^{-1} give better agreement between 2nd and 3rd law values for $\Delta_r H°$ than those derived from $S°$(52 K) = 1.11 cal·K^{-1}·mol^{-1}. Therefore, the value 0.41 cal·K^{-1}·mol^{-1} was not added here.

Fusion Data

T_{fus} and $\Delta_{fus} H°$ were taken from Coughlin *et al.*[8] T_{fus} was reported as 1372°C (1645 K) by Darken and Gurry[9] and as 1369°C (1642 K) by Chipman and Marshall.[6]

$S°(298.15\ K) = 60.799 \pm 0.4\ J \cdot K^{-1} \cdot mol^{-1}$
$T_{trs2} = 598 \pm 3\ K$

$\Delta_f H°(0\ K) = -106.31 \pm 1.7\ kJ \cdot mol^{-1}$
$\Delta_f H°(298.15\ K) = -105.44 \pm 1.7\ kJ \cdot mol^{-1}$
$\Delta_{trs2} H° = 0.398 \pm 0.84\ kJ \cdot mol^{-1}$

Enthalpy of Formation

The adopted value of $\Delta_f H°(298.15\ K)$ is based on the calorimetric determination of Stolyarova and Bezmen[1] assuming that their reported value refers to 298.15 K. This value came from an average of eight determinations of $\Delta_r H°$ for $Fe_{0.877}S(cr) + Zn(cr) \rightarrow ZnS(cr) + 0.877\ Fe(cr)$.

In the composition range $y = 0.095$ to 0.145, Bugli *et al.*[2] determined $\Delta_r H°(433\ K) = -14.4(y\ 0.025)\ kcal \cdot mol^{-1}$ for $Fe S(cr) + yS(l) \rightarrow (1+y)Fe_{1/(1+y)}S(cr)$. Using $y = x/(1-x)$ we calculate that $\Delta_r H°(433\ K) = -14.76x + 0.36\ kcal \cdot mol^{-1}$ for $(1-x)FeS(cr) + xS(l) \rightarrow Fe_{1-x}S(cr)$ in this same composition range. Using $x = 0.123$ and auxiliary JANAF data[3] we can then calculate $\Delta_f H°(Fe_{0.877}S, cr) = -22.1\ kcal \cdot mol^{-1}$ based on Bugli's data. The difference between this value of $\Delta_f H°(298.15\ K)$ and that of Stolyarova and Bezmen is probably due to different morphology of the products; Bugli *et al.* state they are uncertain as to the exact nature of their product. Due to the complicated and kinetically slow phase behavior of $Fe_{0.877}S$, it appears they may not have obtained the pure monoclinic product.

Heat Capacity and Entropy

The adopted heat capacities from 6–350 K are based on our analysis of the $C_p°$ data of Gronvold *et al.*[4] Two small anomalies in the $C_p°$ curve, for which there is no obvious explanation, were observed near 8 and 30 K.[4] These lead to entropy increments of 0.003 and 0.03 cal $K^{-1} \cdot mol^{-1}$, respectively. Since there are no measured $C_p°$ or enthalpy data above 350 K, the $C_p°$ is estimated via the following procedure. Above Tβ, $C_p°$ is estimated as $C_p°(Fe_{0.877}S, cr) - C_p°(FeS, cr) = 0.123\ C_p°(Fe, cr)$ using auxiliary JANAF data.[3] Since the $T\alpha$ transition present in FeS(cr, troilite) is not present in pyrrhotite of composition $Fe_{0.877}S$[3] the heat capacity is assumed to be linear between 350 and 598 K where $C_p°(598\ K)$ is estimated via the procedure outlined above. Hirone *et al.*[5] observed non–linear behavior for $C_p°$ of $Fe_{0.90}S$ from 513 to 593 K.

The value of $S°(298.15\ K)$ is derived from the appropriate integration of $C_p°$ data assuming $S°(6\ K) = 0.0007\ cal \cdot K^{-1} \cdot mol^{-1}$.

Phase Data

The mineral pyrrhotite has a composition range extending from FeS to $Fe_{0.877}S$ ($\sim Fe_7S_8$); the name troilite is reserved for the stoichiometric FeS composition. The data presented in this table refer to the iron poor composition limit which is found to be $Fe_{0.877}S$ below T_{trs2}[6]. For stoichiometric FeS there are 3 crystalline polymorphs designated α, β, γ from low to high temperature, where the α β transition is designated T_{trs1} and the β–γ transition is designated T_{trs2}. We retain this nomenclature for $Fe_{0.877}S$ while recognizing that the α phase does not exist for this composition. Hirone *et al.*[5] found Tβ and ΔHβ° to be independent of composition so we adopt the same values as for FeS(cr, troilite).[3] The transition at 411 K (T_{trs1}) in FeS was found to be non–existent i compositions containing less iron than $Fe_{0.95}S$[2] so it will not be present in $Fe_{0.877}S$. The crystal structure of $Fe_{0.877}S$ is hexagonal above T_{trs2} while the stable form below T_{trs2} is monoclinic.[6,7] The conversion from hexagonal to monoclinic when cooling through T_{trs2} is kinetically slow and even annealing for several months may not be sufficient for complete conversion.[6,7]

Enthalpy of Formation

Zero by definition.

Heat Capacity and Entropy

The current literature was surveyed by Hultgren.[1] Smoothed low temperature heat capacity values are obtained by fitting the data[2-7] graphically and with orthogonal polynomials over selected overlapping temperature intervals. Using $S°(20\ K) = 0.0364\ cal\ K^{-1} \cdot mol^{-1}$, we integrate over the adopted smoothed heat capacity values to obtain $S°(298.15\ K) = 6.529\ cal\ K^{-1} \cdot mol^{-1}$. An uncertainty of 0.015 $cal\ K^{-1} \cdot mol^{-1}$ arises due to the choice of heat capacity values in the region 20–55 K. In this region there is considerable disagreement between the reported heat capacity values of Eucken and Werth,[2] Simon and Swain,[3] and those of Duyckaerts[4] and Keesom and Kurrelmeyer.[5] An additional uncertainty of 0.01 $cal\ K^{-1} \cdot mol^{-1}$ results from the differences in the range 50–298 K in the heat capacity data of Kelley[6] and Stepakoff and Kaufman.[7]

The heat capacity and enthalpy studies above room temperature and numerous. A bibliography of all known studies (including low temperature studies) is available on request. The adopted heat capacity values above 400 K are those selected by Hultgren[8] and Orr and Chipman.[9] The method of orthogonal polynomials is used to join smoothly the low and high temperature heat capacity values. The smooth heat capacity values for metastable α–Fe in the range 1184–1665 K are adjusted from those of Hultgren[8] so as to yield the proper entropy values for γ–Fe. The available heat capacity/enthalpy data show differences up to 10% in $C_p°$ for δ–Fe with the major discrepancies being different slopes in $dC_p°/dT$.

Transition Data

The enthalpies of the α–γ transition at 1184 K and the γ–δ transition at 1665 K are those selected by Hultgren[8] and Orr and Chipman.[9] The α and δ phase has a bcc structure whereas the γ phase has a fcc structure.

Fusion Data

Refer to the liquid table for details.

Sublimation Data

The value adopted for the enthalpy of sublimation is that selected by Hultgren[8] and is based on a 2nd and 3rd law analysis of sublimation data over γ–Fe. Refer to the ideal gas table for details.

PREVIOUS: March 1965 CURRENT: March 1978

$S°(298.15\ K) = 35.545\ J·K^{-1}·mol^{-1}$
$T_{trs1} = 1184 \pm 3\ K\ (\alpha–\gamma)$
$T_{trs2} = 1665 \pm 3\ K\ (\gamma–\delta)$

$\Delta_f H°(298.15\ K) = 7.788\ kJ·mol^{-1}$
$\Delta_{trs1} H° = 0.900 \pm 0.042\ kJ·mol^{-1}$
$\Delta_{trs2} H° = 0.837 \pm 0.084\ kJ·mol^{-1}$

Enthalpy of Formation

The enthalpy of formation at 298.15 K is obtained from that of Fe(α) by adding $\Delta_{trs1}H°$ and the difference between $H°(1184)–H°(298.15\ K)$ of Fe(α] and Fe(γ).

Heat Capacity and Entropy

A current literature survey by Hultgren[1] yielded approximately twenty heat capacity/enthalpy studies which gave information as to the heat capacity of γ–Fe in the stable and metastable region. A listing of these studies is available on request. We adopt the heat capacity values chosen by Hultgren[2] and Orr and Chipman.[3] These values are based primarily on the studies by Dench and Kubaschewski,[4] Braun and Kohlhaas,[5] and Wallace *et al.*[6] However, all the available heat capacity/enthalpy data show discrepancies up to 5% (in $C_p°$); with the major discrepancies appearing as different slopes in $C_p°$ vs T plots. Values are not extended below 298.15 K due to the lack of substantial data in this metastable region. The entropy at 298.15 K is calculated in a manner analogous to that used for the enthalpy of formation.

Transition Data

Refer to the Fe(α, δ) table.[7]

PREVIOUS: CURRENT: March 1978

$S°(298.15\ K) = [34.763]\ J·K^{-1}·mol^{-1}$
$T_{fus} = 1809 \pm 5\ K$ (δ–l)

$\Delta_f H°(298.15\ K) = [12.395]\ kJ·mol^{-1}$
$\Delta_{fus}H° = 13.807 \pm 0.4\ kJ·mol^{-1}$

Enthalpy of Formation

The enthalpy of formation at 298.15 K is calculated from that of the combined phase crystal (α–γ–δ) by adding $\Delta_{fus}H°$ and the difference in enthalpy, $H°(1809\ K)–H°(298.15\ K)$, between the crystal and liquid.

Heat Capacity and Entropy

The heat capacity of the liquid is taken to be 11.0 cal $K^{-1}·mol^{-1}$ as in Hultgren[1] and Orr and Chipman.[2] We adopt this value in the real liquid region as well as in the extrapolated region to 1200 K and to 3500 K. Below 1200 K, heat capacity values are chosen so as to form a curve which joins smoothly the α–Fe heat capacity values in the range 298–500 K. The entropy is calculated in a manner analogous to that used for the enthalpy of formation. A current literature survey[3] revealed numerous heat capacity and enthalpy studies in the liquid region which yielded heat capacity values in the range 8.0 to 12.4 cal $K^{-1}·mol^{-1}$ as given in the table below. The more recent studies by Braun *et al.*,[10] using a quasi–adiabatic calorimeter suggest $C_p° = 10.938$ cal $K^{-1}·mol^{-1}$ whereas the levitation calorimetric enthalpy measurements of Margrave *et al.*[12,14] suggest 10.29 ± 0.29 and 11.138 ± 0.43 cal $K^{-1}·mol^{-1}$ respectively.

Fusion Data

The adopted T_{fus} and $\Delta_{fus}H°$ values are those selected by Hultgren[1] and Orr and Chipman;[2] 1809 ± 5 K and 3300 ± 100 cal·mol^{-1}, respectively. Reported values for $\Delta_{fus}H°$ vary from a low of 2760 to a high of 3865 cal·mol^{-1}, as given in the table below.

Vaporization Data

The boiling point is calculated from the adopted thermodynamic functions and the chosen enthalpy of sublimation so that the Gibbs energy functions calculated by integration of the crystal–liquid data and by statistical methods for the gas phase are equal at T_{vap}.

Reference	Year	Calorimetric Method	T_{fus}, K	$\Delta_{fus}H°$ kcal·mol^{-1}	$C_p°(l)$ cal $K^{-1}·mol^{-1}$	T/K

Enthalpy of Formation

The sublimation and vaporization studies on iron are too numerous to tabulate. A current literature survey by Hultgren yielded approximately thirty investigations.[1] As in Hultgren,[2] we adopt $\Delta_f H°$(Fe, g, 298.15 K) = 99.3 ± 0.3 kcal·mol^{-1} based on the studies of Morris *et al.*[3] and Myles and Aldred.[4] A complete listing of all vapor pressure studies is available on request. Many of the more recent studies do not provide sufficient information to enable calculation of enthalpy of formation values via the 2nd and 3rd law approach.

Our 2nd and 3rd law analyses of the vaporization data of Morris *et al.*[3] and the sublimation data of Myles and Aldred[4] are given below.

Source	Data Points	T/K	$\Delta_f H°$(298.15 K), kcal·mol^{-1} 2nd law	3rd law	Drift cal·K^{-1}·mol^{-1}	$\Delta_f H°$(298.15 K) kcal·mol^{-1}
Fe(l) = Fe(g)	21	1812–1891	96.8 ± 1.1	96.5 ± 0.1	0.1 ± 6	99.5
Fe(γ) = Fe(g)	eqn	1450–1650	98.1	97.1	−0.6	99.0

Heat Capacity and Entropy

The electronic energy levels are given in the compilation by Reader and Sugar.[5] Although we have only listed the ground state, the lowest four excited states, the highest observed excited state, and the ionization limit for Fe(g), all levels listed by Reader and Sugar,[5] as well as estimated missing levels, are used in the calculations. The observed levels are too numerous to list completely. Our calculations indicate that for Fe(g) the thermochemical functions are independent of the estimated missing levels (for $n = 4, 5, 6, 7$) and the cutoff procedure up to 3500 K. The Gibbs energy function is essentially unaffected up to 5200 K. The reported uncertainty in $S°(298.15\ K)$ is due to uncertainties in the relative atomic mass and the fundamental constants. Extension of these calculations above 6000 K may require consideration of the higher excited states and utilization of proper fill and cutoff procedures.[6] In fact, the inclusion of some higher states ($n = 4, 5, 6, 7$) and consideration of various cut–off procedures leads to calculational differences in the Gibbs energy function of roughly 0.1 cal·K^{-1}·mol^{-1} or greater at temperatures in excess of 8000 K.

Enthalpy of Formation

$\Delta_f H°(Fe^+, g, 0 K)$ is calculated from $\Delta_f H°$(Fe, g, 0 K)[1] using the spectroscopic value of IP(Fe) = 63480 ± 500 cm^{-1} (759.390 ± 5.98 $kJ·mol^{-1}$) from Corliss and Sugar.[2] The ionization limit is converted from cm^{-1} to $kJ·mol^{-1}$ using the factor, 1 cm^{-1} = 0.01196266 $kJ·mol^{-1}$, which is derived from the 1973 CODATA fundamental constants.[3] Rosenstock *et al.*[4] and Levin and Lias[5] have summarized additional ionization and appearance potential data.

$\Delta_f H°(Fe^+, g, 298.15 K)$ is calculated from $\Delta_f H°$(Fe, g, 0 K) by using IP(Fe) with JANAF[1] enthalpies, $H°(0 K)-H°(298.15 K)$, for Fe(g), Fe^+(g), and e^-(ref). $\Delta_f H°(Fe \rightarrow Fe^+ + e^-, 298.15 K)$ differs from a room temperature threshold energy due to inclusion of these enthalpies and to threshold effects discussed by Rosenstock *et al.*[4] $\Delta_f H°$(298.15 K) should be changed by −6.197 $kJ·mol^{-1}$ if it is to be used in the ion convention that excludes the enthalpy of the electron.

Heat Capacity and Entropy

The information on electronic energy levels and quantum weights, given by Corliss and Sugar,[2] is incomplete because many theoretically predicted levels have not been observed. Although we have listed only five levels for Fe^+(g), all levels listed by Corliss and Sugar,[2] as well as estimated levels, are used in the calculation. The observed levels are too numerous to list completely. The calculations indicate that for Fe^+(g), the thermodynamic functions are independent of the estimated missing levels (for n=4), the cut–off procedure, and the inclusion of n=5 levels up to 6000 K; the Gibbs energy function showing no significant variations at this temperature. The reported uncertainty in $S°$(298.15 K) is due to uncertainties in the relative ionic mass, and the fundamental constants. Extension of these calculations above 6000 K may require consideration of the higher excited states (n>5), and use of different fill and cut–off procedures.[6]

$^4F_{3/2}$	1200	4

Enthalpy of Formation

$\Delta_f H°(Fe^-, g, 0\ K)$ is calculated from $\Delta_f H°(Fe, g, 0\ K)$[1] using the adopted electron affinity of EA(Fe) = 0.163 ± 0.035 eV (15.727 ± 3.377 $kJ·mol^{-1}$). This value, recommended by Hotop and Lineberger,[2] is based on a laser photodetachment electron spectrometry study.[3] Additional information on Fe^-(ref) may be obtained in the critical discussions of Hotop and Lineberger,[2,4] Rosenstock *et al.*[5] and Massey.[6]

$\Delta_f H°(Fe^-, g, 298.15\ K)$ is obtained from $\Delta_f H°(Fe, g, 0\ K)$ by using EA(Fe) with JANAF[1] enthalpies, $H°(0\ K) - H°(298.15\ K)$, or Fe^-(ref), Fe(g), and e^-(ref). $\Delta_f H°(Fe^- \rightarrow Fe + e^-, 298.15\ K)$ differs from a room-temperature threshold energy due to inclusion of these enthalpies and to threshold effects discussed by Rosenstock *et al.*[5] $\Delta_f H°(298.15\ K)$ should be changed by + 6.197 $kJ·mol^{-1}$ if it is to be used in the ion convention that excludes the enthalpy of the electron.

Heat Capacity and Entropy

The ground state electronic configuration for Fe^-(ref) is given by Hotop and Lineberger[2,4] and Rosenstock *et al.*[5] The fine structure separations in the ground state have been calculated by an isoelectronic extropolation of ratios of fine structure separations.[7]

$S°(298.15\ K) = [87.864 \pm 8.4]\ J \cdot K^{-1} \cdot mol^{-1}$
T_{fus} = Unknown

$\Delta_f H°(0\ K)$ = Unknown
$\Delta_f H°(298.15\ K) = -574.04 \pm 2.9\ kJ \cdot mol^{-1}$
$\Delta_{fus} H°$ = Unknown

Enthalpy of Formation

The enthalpy of combustion of $Fe(OH)_2$(cr), according to the chemical reaction $Fe(OH)_2(cr) + 1/4\ O_2(g) = 1/2\ Fe_2O_3(cr) + H_2O(l)$ was determined to be -29.8 ± 0.65 kcal·mol^{-1} by Fricke and Rihl.[1] From these data the adopted enthalpy of formation, $\Delta_f H°(298.15\ K)$, was evaluated to be -137.2 ± 0.7 kcal·mol^{-1}.

The enthalpy changes for the following three reactions were determined by Thomsen.[2]

Reaction	$\Delta_r H°(291\ K)$, kcal·mol^{-1}
$FeCl_2(cr) = FeCl_2\ (400\ H_2O)$	−17.9
$FeCl_2(200\ H_2O) + H_2SO_4(200\ H_2O) = FeSO_4(200\ H_2O) + 2\ HCl(100\ H_2O)$	−3.6
$FeSO_4(aq) + 2\ KOH(aq) = Fe(OH)_2(cr) + K_2SO_4(aq)$	−6.34

Using $\Delta_f H°(298.15\ K) = -81.7$ kcal·mol^{-1} for $FeCl_2$(cr) and those for the other compounds in aqueous solution (assuming aq. = 200 H_2O in Reaction 3) obtained from Wagman *et al.*[3] the enthalpy of formation at 298.15 K for $Fe(OH)_2$(cr) was derived as -135.8 kcal·mol^{-1} which agrees reasonably with the adopted value.

Heat Capacity and Entropy

The heat capacities, 298.15–700 K and $S°(298.15\ K)$ were estimated by comparison with those for $FeCl_2$(cr), $CaCl_2$(cr) and $Ca(OH)_2$(cr). The $C_p°$ values above 700 K were obtained by graphical extrapolation of the $C_p°$ curve plotted using the above $C_p°$ values.

Sublimation Data

The value of $\Delta_{sub} H°(298.15\ K)$ was calculated as the difference between $\Delta_f H°(298.15\ K)$ for $Fe(OH)_2$(g) and $Fe(OH)_2$(cr).

Point Group: $[C_{2h}]$ $\sigma = 2$

Bond Distances: Fe–O = [1.8] Å O–H = [0.96] Å

Bond Angles: O–Fe–O = [180]° Fe–O–H = [105]°

Product of the Moments of Inertia: $I_A I_B I_C = [9.90391 \times 10^{-116}]\ g^3·cm^6$

Enthalpy of Formation

The equilibrium constants, at temperatures between 1300 and 1460°C, for the chemical reaction $Fe(cr) + 2\ H_2O(g) = Fe(OH)_2(g) + H_2(g)$ were determined by Belton and Richardson.[1] Using these data, the enthalpy change, $\Delta_r H°$ (298.15 K), of the reaction is evaluated to be 35.53 ± 3.0 and $36.57\ kcal·mol^{-1}$ by the 2nd and 3rd law method, respectively. Based on the 3rd law value for $\Delta_f H°(298.15\ K)$, the enthalpy of formation, $\Delta_f H°(Fe[OH]_2, g, 298.15\ K)$, is calculated to be $-79 \pm 0.5\ kcal·mol^{-1}$.

Heat Capacity and Entropy

The molecular structure is assumed to be the same as that for $B(OH)_2(g)$. The Fe–O bond distance is taken from FeO(g). The O–H bond distance and Fe–O–H bond angle are estimated from those for $H_2O(g)$. The vibrational frequencies, and electronic levels and quantum weights are obtained by comparison with those for $B(OH)_2(g)$ and $FeCl_2(g)$, respectively. These values are adjusted to give reasonable 2nd and 3rd law agreements. The principal moments of inertia are: $I_A = 0.2814 \times 10^{-39}$, $I_B = 18.6208\ 10^{-39}$, and $I_C = 18.9022 \times 10^{-39}\ g·cm^2$.

Enthalpy of Formation

Schindler *et al.*[1] investigated the solubility of aged $Fe(OH)_3$ precipitates by determining the Fe^{++} + and H^+ ion concentration of solution in contact with the solid phase. The ion concentration was measured by the EMF–method at the constant ionic strength 3M $NaClO_4$(solution). The precipitates were investigated by X–ray and electron microscope methods. The equilibrium constant was derived as log $[Fe^{+++}][H^+]^3$ = log K = 3.55 ± 0.1 for amorphous inactive hydroxide at 25°C. From these data the quantity log Ks = −39.1 ± 0.2 was evaluated where Ks is the solubility product of $Fe(OH)_3$. The Gibbs energy change, $\Delta_r G°$(298.15 K), of the reaction $Fe(OH)_3$(cr) = Fe^{+++}(aq) + 3 OH^-(aq) was calculated to be 53.34 ± 0.27 kcal·mol^{-1}. Using $S°$(298.15 K) = −70.1 and 2.57 cal·K^{-1}·mol^{-1} for Fe^{+++}(aq) and OH^-(aq), respectively, and an estimated $S°$($Fe(OH)_3$, cr, 298.15 K) = 25 cal·K^{-1}·mol^{-1}, the enthalpy change, $\Delta_r H°$(298.15 K) of the reaction is calculated to be 22.69 kcal·mol^{-1}, according to the relationship $\Delta H = \Delta F + T\Delta S$. The entropy values for Fe^{++} + and OH^- ions, were obtained from[2] and[3] respectively. Based on $\Delta_f H°$(Fe^{+++}, aq, 298.15 K) = −11.4 and $\Delta_f H°$(OH^-, aq, 298.15 K) = −54.97 kcal·mol^{-1}, taken from the same sources, the enthalpy of formation, $\Delta_f H°$(298.15 K), for $Fe(OH)_3$(cr) was evaluated to be −199 ± 3 kcal·mol^{-1}, which was adopted here.

The divergent values for solubility product (SP) of $Fe(OH)_3$ found in the literature may be due, not only to the various forms of precipitate but also to the tendency to form colloidal solutions. The SP values for $Fe(OH)_3$ were also reported by Evans and Pryor[4] Kriukor and Awsejewitsch[5] Ruff and Hirsch[6] Britton[7] and Jellinek and Gorden.[8]

The enthalpy changes, $\Delta_r H°$(291 K), for the reactions: (1) $FeCl_3$(aq) + 3NaOH(aq) = $Fe(OH)_3$(cr) + 3NaCl(aq) and (2) $FeCl_3$(cr) = $FeCl_3$(aq) were determined to be −24.50 and −31.68 kcal·mol^{-1}, respectively by Thomsen.[9] Assuming the aqueous solutions all contain 200 mol of H_2O, the enthalpy of formation, $\Delta_f H°$(298.15 K), for $Fe(OH)_3$ was calculated as −196.9 kcal·mol^{-1} from Reaction (1) and (2). The $\Delta_f H°$(298.15 K) values for NaOH(aq) and NaCl(aq) were obtained from Parker[10] and JANAF $\Delta_f H°$(298.15 K) values for NaOH(cr) and NaCl(cr).

Heat Capacity and Entropy

The heat capacities, 298.15–1000 K, were estimated by comparison with those for B_2O_3(cr), Fe_2O_3(cr) and $B(OH)_3$(cr). The $C_p°$ values above 1000 K were obtained by graphical extrapolation. The $S°$($Fe(OH)_3$, cr, 298.15 K) value was estimated by comparison with that for $B(OH)_3$(cr).

Enthalpy of Formation

The chemical equilibrium of the decomposition of FeI_2(cr), 771.15–858.15 K, has been studied by Zaugg and Gregory.[1] Using the reported partial pressures for I_2(g), the enthalpy change, $\Delta_rH°(298.15\ K)$, for the reaction $FeI_2(cr) = Fe(cr) + I_2(g)$ was evaluated by both the 2nd and 3rd law methods to be 39.79 ± 1.0 and 39.69 ± 0.3 kcal·mol^{-1}, respectively. Based on the 3rd law $\Delta_rH°(298.15\ K)$ value, the enthalpy of formation, $\Delta_fH°(298.15\ K)$ for FeI_2(cr) was calculated as −25 kcal·mol^{-1} which was adopted here.

The enthalpy change for the reaction $FeI_2(cr) = Fe^{++}(aq) = 2\ I^-(aq)$ was determined to be −19.46 ± 0.03 kcal·mol^{-1} by Paoletti *et al.*[2] using a solution calorimetric method. Adopting $\Delta_fH°(298.15\ K) = -21.3$ and −13.19 kcal·mol^{-1} for Fe^{++}(aq) and I^-(aq), respectively, the value of $\Delta_fH°(FeI_2, cr, 298.15\ K)$ was derived as −28.22 ± 1 kcal·mol^{-1}. The value of $\Delta_fH°(I^-, aq, 298.15\ K)$ was taken from Wagman *et al.*[3] The value of $\Delta_fH°(Fe^{++}, aq, 298.15\ K)$ was derived from enthalpy of solution and formation for $FeCl_2$(cr).

The enthalpies of solution of Fe(cr), I_2(cr) and FeI_2(cr) in aqueous Br_2–KBr solution were measured by Hieber and Woerner[4] using an ice calorimeter. From the results obtained the enthalpy of formation for FeI_2(cr) was reported as −30.1 kcal·mol^{-1}.

Heat Capacity and Entropy

The heat capacities, 343.15–773.15 K, were measured by Oetting and Gregory.[5] The $C_p°$ value at temperatures below 343.15 and above 773.15 K were estimated by graphic extrapolation. The low temperature heat capacities, 11–130 K were determined by Miljutin and Parfenowa.[6] These data appear to be inadequate for the derivation of the entropy at 298.15 K. The value of $S°(298.15\ K)$ adopted was calculated from the entropy change, $\Delta_rS°(298.15\ K) = 28.7\ cal·K^{-1}·mol^{-1}$, for the decomposition reaction $FeI_2(cr) = Fe(cr) + I_2(g)$, obtained by the second law analysis on the equilibrium pressure data reported by Zaugg and Gregory.[1]

Transition Data

A minor transition in the vicinity of 370°C (360–385°C) has been reported by Oetting and Gregory.[5] Subsequent studies by Wydeven[7] have shown the magnitude of the transition to be sensitive to trace amounts of impurities, but the nature of the transition has not been clearly established. A magnetic transition at 10 K was reported by Bizette *et al.*[8] The $\Delta_{trs}H°$ value was evaluated from the heat capacity–temperature plot given by Oetting and Gregory.[5]

Fusion Data

T_{fus} was reported by Fischer and Gewehr.[9] $\Delta_{fus}H°$ was estimated by comparison with that for $FeBr_2$(cr).

Sublimation Data

$\Delta_{sub}H°(cr \rightarrow monomer, 298.15\ K)$ is calculated as the difference between $\Delta_fH°(298.15\ K)$ for FeI_2(g) and FeI_2(cr). $\Delta_{sub}H°(cr \rightarrow dimer, 298.15\ K)$ was calculated as the difference between those for Fe_2I_4(g) and 2 FeI_2(cr).

$S°(298.15\ K) = [195.430]\ J·K^{-1}·mol^{-1}$ $\Delta_fH°(298.15\ K) = [-71.046]\ kJ·mol^{-1}$
$T_{fus} = 860 \pm 2\ K$ $\Delta_{fus}H° = 44.769\ kJ·mol^{-1}$

Enthalpy of Formation

$\Delta_fH°(FeI_2, l, 298.15\ K)$ is calculated from $\Delta_fH°(FeI_2, cr, 298.15\ K)$ by adding the enthalpy of fusion, $\Delta_{fus}H°$, and the difference in enthalpy, $H°(860\ K)–H°(298.15\ K)$, between the crystal and liquid.

Heat Capacity and Entropy

The heat capacity is assumed to be constant in the temperature range from 298.15 to 2000 K and is calculated on the assumption that $C_p° = 9.0\ cal·K^{-1}\ g·atom^{-1}$ for FeI_2(l). $S°(FeI_2, l, 298.15\ K)$ is calculated in a manner analogous to that used for the enthalpy of formation.

Vaporization Data

T_{vap} is the temperature at which the vapor pressure of FeI_2(g) and Fe_2I_4(g) over FeI_2(l) equals one bar. The value of $\Delta_{vap}H°$ is derived from the vapor composition and the enthalpies of vaporization of FeI_2(l) to monomer and dimer at T_{vap}.

Enthalpy of Formation

The chemical equilibria for the reactions: (A) FeI_2(cr) = FeI_2(g), (B) FeI_2(l) = FeI_2(g), and (C) Fe(cr) + 2 I(g) = FeI_2(g), have been studied by several investigators. Based on the equilibrium pressures reported, the corresponding enthalpy changes were evaluated by both the 2nd and 3rd law method. The results obtained are presented in the table below. Using the third law $\Delta_f H°(298.15\ K)$ values, the enthalpy of formation for FeI_2(g) were calculated. The adopted value for $\Delta_f H°(FeI_2, g, 298.15\ K)$ is 21.0 ± 3 $kcal·mol^{-1}$. The disagreement between the sets of 2nd and 3rd law $\Delta_f H°(298.15\ K)$ values listed in the table may be due to the presence of dimer, Fe_2I_4(g) which was not accounted for in deriving the partial pressure of FeI_2(g). The data obtained from Schoonmaker *et al.* was corrected for the presence of dimer. However, only one point value was given.

Source	Reaction	T/K	Method	$\Delta_r H°(298.15\ K)$, $kcal·mol^{-1}$ 2nd law	3rd law	Drift $cal·K^{-1}·mol^{-1}$	$\Delta_f H°(298.15\ K)$, $kcal·mol^{-1}$

*The vapor pressure data used for evaluation were those corrected by Zaugg and Gregory.[4]

Heat Capacity and Entropy

The molecular structure was assumed to be linear. The Fe–I bond distance was estimated by Brewer *et al.*[5] The vibrational frequencies were estimated so that the derived Gibbs energy fucntions yielded 2nd and 3rd law $\Delta_r H°(298.15\ K)$ values in reasonable agreements, see the above table. The electronic levels and quantum weights were estimated from those for $FeCl_2$(g) reported by DeKock and Gruen.[6]

PREVIOUS: September 1966 (1 atm) CURRENT: September 1966 (1 bar)

$S°(298.15\ K) = [60.752]\ J·K^{-1}·mol^{-1}$
$T_{fus} = [1650]\ K$

$\Delta_f H°(0\ K) = Unknown$
$\Delta_f H°(298.15\ K) = [-272.044]\ kJ·mol^{-1}$
$\Delta_{fus} H° = [24.058]\ kJ·mol^{-1}$

Enthalpy of Formation

The value of $\Delta_f H°(298.15\ K)$ for FeO(cr) was derived based on an assumption that at 1650 K, $\Delta_f F°$(FeO, cr) = $\Delta_f F°$(FeO, l). From the value $\Delta_f F°$(FeO, cr, 1650 K) = −39.77 kcal·mol^{-1}, $\Delta_f H°$(FeO, cr, 1650 K) was calculated to be −63.97 kcal·mol^{-1}, yielding $\Delta_f H°$(FeO, cr, 298.15 K) = −65.02 kcal·mol^{-1} (−272.044 kJ·mol^{-1}).

Heat Capacity and Entropy

The $C_p°$ values were estimated assuming $C_p°$ (FeO, cr) = $C_p°$(Wustite, cr) + 0.053 $C_p°$(Fe, cr). The $C_p°$ values obtained were plotted. The adopted $C_p°$ points were taken from the smoothed $C_p°$ curve. $S°(298.15\ K)$ for FeO(cr) was calculated as $S°$(FeO, cr) = $S°$ (Wustite, cr) + 0.053 $S°$(Fe, cr) + $\Delta S°$(mixing) where $\Delta S°$ is the entropy of mixing (0.41 cal K^{-1}·mol^{-1}).

Fusion Data

T_{fus} is assumed to be the same as that for Wustite. The difference between $\Delta_f H°(1650\ K)$ for FeO(l) and FeO(cr) is $\Delta_{fus} H°$.

Sublimation Data

$\Delta_{sub} H°(298.15\ K)$ is calculated as the difference between $\Delta_f H°(298.15\ K)$ for FeO(g) and FeO(cr).

$S°(298.15\ K) = 75.415\ J·K^{-1}·mol^{-1}$
$T_{fus} = [1650]\ K$

$\Delta_f H°(298.15\ K) = [-249.532]\ kJ·mol^{-1}$
$\Delta_{fus} H° = [24.058]\ kJ·mol^{-1}$

Enthalpy of Formation

The enthalpy of formation, $\Delta_f H°$(FeO, l, 298.15 K), is evaluated based on as assumption that the enthalpy of fusion of O_2(g). In other words, during melting the Wustite releases O_2(g) and converts tp FeO(l).

Heat Capacity and Entropy

The enthalpy changes, $H°(T)-H°(298.15\ K)$, for 1650–1800 K of liquid iron oxide were determined by Coughlin *et al.*[1] The $C_p°$ (FeO, l) was derived as 16.3 $cal·K^{-1}$. This value was adopted as the heat capacity for FeO(l) up to 4000 K. A glass transition temperature was assumed at 1100 K. $S°$(FeO, l, 298.15 K) is calculated based on an assumption that the entropy of fusion of Wustite represents also the entropy change of the reaction. $Fe_{0.947}O(cr) = 0.947\ FeO(l) + (0.053/2)\ O_2(g)$. From the entropy of fusion, $\Delta_{fus} H°(1650\ K) = 4.539\ cal·K^{-1}·mol^{-1}$, the value $S°$(FeO), l, 298.15 K) = 18.029 $cal·K^{-1}·mol^{-1}$ was derived.

Fusion Data

The melting point (T_{fus}) for Wustite ($Fe_{0.947}O$, cr) has been reported by many investigators. However, the composition of the liquid state of Wustite was not identified. An assumption was made that during melting the reaction $Fe_{0.947}O(cr) = 0.947\ FeO(l) + (0.053/2)\ O_2(g)$ occurs. Hence the related thermodynamic properties were derived.

Decomposition Data

T_{dcm} is the temperature at which $\Delta_f G°$ equals zero.

$\omega_e = 880.0\ cm^{-1}$ $\omega_e x_e = 5.0\ cm^{-1}$ $\sigma = 1$

$B_e = [0.4184]\ cm^{-1}$ $\alpha_e = [0.00293]\ cm^{-1}$ $r_e = [1.8]$ Å

Enthalpy of Formation

The enthalpy of formation for FeO(g) is not well established at the present time. The values of $\Delta_f H°$(FeO, g, 298.15 K) derived from the following reactions: (A) FeO(g) = Fe(g) + O(g) , (B) FeO(g) + 1/2 O_2(g), and (C) FeO(l) = FeO(g), are not in agreement. There are three $D_0°$(Fe–O) values reported for reaction (1). The enthalpy change for reaction (2) was evaluated based on the partial pressure data (PFeO/PFe) = 0.2 at 1600°C, measured by Washburn,[4] using a mass spectrometric method,[6] and $PO_2 = 1.66 \times 10^{-6}$ atm reported by Darken and Gurry.[7] The enthalpy value for reaction (3) was calculated based on the reported value, $\Delta_{vap}H°(2785\ K) = 96.096\ kcal·mol^{-1}$ determined by Burtsev *et al.*[5] The results obtained are presented as follows. The value of $\Delta_f H°(298.15\ K)$ for FeO(g) adopted is 60 ± 5 $kcal·mol^{-1}$.

Source	Reaction	Method	$\Delta_r H°(298.15\ K)$, $kcal·mol^{-1}$	$\Delta_f H°(298.15\ K)$ $kcal·mol^{-1}$
Herzberg[1]	A	Spectroscopic	111.9	47.2
Gaydon[2]	A	Spectroscopic	93.4 ± 23.1	65.7 ± 23.1
Lagerqvist and Huldt[3]	A	Spectroscopic	99.0 ± 11.6	60.1 ± 11.6
Washburn *et al.*[4]	B	Spectroscopic	99.3 ± 5	59.8 ± 5
Burtsev *et al.*[5]	C	Transpiration	111.8	52.2

Heat Capacity and Entropy

Since the ground state configuration is mainly that due to Fe^{++} in a ligand field, it was assumed to be the same as that for $FeCl_2$(g) reported by DeKock and Gruen.[8] The electronic levels and quantum weights were estimated by comparison with those for $FeCl_2$(g). The values of ω_e and $\omega_e x_e$ were taken from Herzberg.[1] The bond distance was calculated according to the method suggested by Guggenheimer,[9] assuming FeO(g) as a polar molecule. The value of B_e was calculated by use of the relationship: $B_e = (2.799076 \times 10^{-39})/I$ where I is the moment of inertia of FeO(g). The value of α_e was derived from ω_e, $\omega_e x_e$ and B_e by the method suggested by Herzberg.[1]

$S°(298.15\ K) = 120.957 \pm 1.3\ J·K^{-1}·mol^{-1}$

$\Delta_f H°(0\ K) = -919.33 \pm 8.4\ kJ·mol^{-1}$

$\Delta_f H°(298.15\ K) = -928.85 \pm 8.4\ kJ·mol^{-1}$

Enthalpy of Formation

The enthalpy change for the reaction $FeSO_4(cr) = FeSO_4(110 \infty H_2O)$ was determined to be $-14.9\ kcal·mol^{-1}$ by Forcrand.[1] Using $\Delta_f H°(298.15\ K) = -345.85\ kcal·mol^{-1}$ for $FeSO_4(110 \infty H_2O)$, the enthalpy of formation (298.15 K) for $FeSO_4$(cr) was calculated as $-221\ kcal·mol^{-1}$. The value of $\Delta_f H°(FeSO_4$, cr, 298.15 K) was estimated based on $\Delta_f H°(298.15\ K) = 235.9\ kcal·mol^{-1}$ for $FeSO_4(200 \infty H_2O) + H_2SO_4(200\ H_2O) = FeSO_4(200\ H_2O) + 2HCl(100 \infty H_2O)$ measured by Thomsen.[2] See the $Fe(OH)_2$(cr) table for details.

The decomposition pressures of $FeSO_4$(cr) at different temperatures were investigated by D'Ans[3] and Greulich.[4] Using their reported partial pressures for SO_3(g) and SO_2(g), the enthalpy change for the reaction $2FeSO_4(cr) = Fe_2O_3(cr) + SO_3(g) + SO_2(g)$ was evaluated by both the 2nd and 3rd law methods. The results obtained are presented in the following table.

Source	T/K	$\Delta_r H°(298.15\ K)$, kcal·mol^{-1} 2nd law	3rd law	$\Delta_f H°(298.15\ K)$ kcal·mol^{-1}
D'Ans[3](1905)	753.15–908.15	83.2 ± 4.6	82.7 ± 1.1	−222.7
Greulich[4](1927)	887.15–971.15	64.8 ± 8.8	80.1 ± 1.4	−221.5
Neumann and Heintke[5](1937)	633.15–862.15	72.4 ± 5.4	75.3 ± 0.5	−219.1

The decomposition pressures asumed for the same reaction have been determined by Neumann and Heintke.[5] From their data the partial pressures for SO_3(g) and SO_2(g) were evaluated. Using the derived SO_3(g) and SO_2(g) partial pressures, the corresponding enthalpy change for the reaction were calculated by both the 2nd and 3rd law methods. The results obtained are also listed in the same table.

The value of $\Delta_f H°(298.15\ K)$ for $FeSO_4$(cr) is selected as $222 \pm 2\ kcal·mol^{-1}$.

Heat Capacity and Entropy

The low temperature heat capacities, 50.12 294.9 K, were determined by Moore and Kelley.[6] Based on $S°(50.12\ K) = 2.10\ cal·K^{-1}·mol^{-1}$, the value of $S°(FeSO_4$, cr, 298.15 K) was reported to be $25.71 \pm 0.2\ cal·K^{-1}·mol^{-1}$. Using the Gibbs energy functions for $FeSO_4$(cr) based on this $S°(298.15\ K)$ value, to evaluate the vapor pressure data for Reaction,[1] the 2nd and 3rd law values of $\Delta_f H°(298.15\ K)$ were derived as 72.36 ± 7.60 and $86.51 \pm 1.26\ kcal·mol^{-1}$, respectively. Since the report by Moore and Kelley[6] did not mention the magnetic entropy contribution, an attempt was made to add 3.20 (=Rln5) $cal·K^{-1}·mol^{-1}$ to $S°(FeSO_4$, cr, 298.15 K) and reevaluate the decomposition pressure data. The results obtained were better than before, see the paragraph on "Enthalpy of Formation," for details. Therefore the value, $S°(298.15\ K) = 25.71 + 3.2 = 28.91\ cal·K^{-1}·mol^{-1}$ for $FeSO_4$(cr), was adopted. The heat capacities above 294.9 K were estimated by comparison with those for $MnSO_4$(cr). The high temperature heat capacities, 870.3–1082.3 K, were determined by Southard and Shomate[7]. The two sets of data were joined smoothly at 298.15 K by use of Shomate–function plot.

Decomposition Data

$T_{dcm} = 944$ K is the temperature at which the vapor pressure of the gaseous decomposition products equals one atmosphere, which was obtained by graphical interpolation of the decomposition pressure data on $FeSO_4$(cr), reported by Greulich.[4]

$S°(298.15\ K) = 60.321 \pm 0.04\ J·K^{-1}·mol^{-1}$
$T_{trs1} = 411 \pm 3\ K$
$T_{trs2} = 598 \pm 3\ K$
$T_{fus} = 1463 \pm 3\ K$

$\Delta_f H°(0\ K) = -102.17 \pm 0.8\ kJ·mol^{-1}$
$\Delta_f H°(298.15\ K) = -101.67 \pm 0.8\ kJ·mol^{-1}$
$\Delta_{trs1} H° = 1.665 \pm 0.8\ kJ·mol^{-1}$
$\Delta_{trs2} H° = 0.397 \pm 0.08\ kJ·mol^{-1}$
$\Delta_{fus} H° = 31.464 \pm 2.1\ kJ·mol^{-1}$

Enthalpy of Formation

The adopted $\Delta_f H°(298.15\ K)$ is $24.30 \pm 0.2\ kcal·mol^{-1}$ and is based on our 3rd law analysis of gas phase H_2S/H_2 equilibrium data of.[1-7] Additional studies of a similar nature are reported by Mills.[8] The gas phase equilibrium results are favored over calorimetric[8] and emf[9-11] results because of greater certainty in the stoichiometry of the iron sulfide. Of the calorimetric studies[8] only those of Adami and King ($\Delta_f H°(298.15\ K) = -23.89 \pm 0.41\ kcal·mol^{-1}$) and the annealed sample of Ariya *et al.* ($\Delta_f H°(298.15\ K) = -24.4\ kcal·mol^{-1}$) are in reasonable agreement with the adopted value. Of the emf results, all refer to less than stoichiometric composition $Fe_{0.95}S$[9] $Fe_{0.98}S$[10] or to impure sample, 97.58%.[11] $\Delta_f H°(298.15\ K)$ has been shown to vary significantly as a function of stoichiometry[12] which is a result of the variation of $\Delta_\alpha H°$ with composition.[12]

Heat Capacity and Entropy

The adopted heat capacities are obtained by merging the $C_p°$ data (7–345 K) of Gronvold *et al.*[13] and the enthalpy data (356–1488 K) of Coughlin.[14] The data are difficult to merge smoothly because of the proximity of the α β transition at 411 K. Coughlin gives the composition of his sample as $FeS_{1.02}$ and this introduces some uncertainty at the higher temperatures.

The value of $S°(298.15\ K)$ is obtained from the appropriate integration of $C_p°$ values assuming $S°(7\ K) = 0.0028\ cal·K^{-1}·mol^{-1}$.

Phase Data

The mineral pyrrhotite has a composition range extending from FeS to $Fe_{0.875}S$ (Fe_7S_8); the name troilite is reserved for the stoichiometric FeS composition. The phase diagram[15] of this system shows that the iron rich limit of this phase corresponds to stoichiometric FeS below 1370 K; above this temperature only an iron deficient material exists so that stoichiometric FeS will melt incongruently.

There are two solid state phase transitions, both associated with electronic magnetic phenomena. The adopted temperature of the α β transition is $T_{trs1} = 411 \pm 3$ K.[15] Our analysis of the adopted $C_p°$ data yields $\Delta_{trs1} H° = 0.398\ kcal·mol^{-1}$; in view of the uncertainties in these data we adopt an uncertainty of $\pm 0.2\ kcal·mol^{-1}$ in $\Delta_{trs1} H°$. The adopted temperature of the β–γ transition is $T_{trs2} = 598 \pm 3$ K[15] and our analysis of Coughlin's high temperature enthalpy data[14] yields $\Delta_{trs2} H° = 0.095 \pm 0.02\ kcal·mol^{-1}$.

Fusion Data

Refer to the liquid table for details.

Iron Sulfide (FeS) LIQUID M_r = 87.907

$S°(298.15\ K) = [82.811]\ J·K^{-1}·mol^{-1}$ $\Delta_f H°(298.15\ K) = [-68.811]\ kJ·mol^{-1}$

$T_{fus} = 1463 \pm 3\ K$ $\Delta_{fus}H° = 31.464 \pm 2.1\ kJ·mol^{-1}$

Enthalpy of Formation

$\Delta_f H°$(FeS, l, 298.15 K) is calculated from that of the crystal by adding the enthalpy of fusion, $\Delta_{fus}H°$, and the difference in enthalpy, $H°(1463\ K)–H°(298.15\ K)$, between the crystal and liquid.

Heat Capacity and Entropy

The heat capacity of liquid FeS above an assumed glass transition temperature of 1050 K is taken from Vaisburd and Zedina.[2] Their constant value of $C_p° = 14.95\ cal·K^{-1}·mol^{-1}$ is lower than $C_p° = 17.8\ cal·K^{-1}·mol^{-1}$ which we derive from the enthalpy data of Coughlin.[3] The latter value is based on two points separated by only 9 K while the results of Vaisburd and Zedina are quoted as covering the range from the mp to 1723 K. The heat capacity below the glass transition is that of the crystal.[1]

$S°$(FeS, l, 298.15 K) is calculated in a manner analogous to that used for the enthalpy of formation.

Fusion Data

The adopted melting point of 1463 ± 3 K is taken from the phase diagram of Hansen and Anderko.[4] The adopted enthalpy of fusion, $\Delta_{fus}H° = 7.52 \pm 0.5\ kcal·mol^{-1}$, is from our analysis of the high temperature enthalpy data of Coughlin.[3]

Enthalpy of Formation

Drowart *et al.*[1] used a modified Knudsen cell and a mass spectrometric technique to study the equilibrium FeS(g) + Mn(g) = MnS(g) + Fe(g). We adopt a value of $D_0° = 76.3 \pm 3.5\ kcal\cdot mol^{-1}$ based on their 3rd law analysis of this equilibrium. With auxiliary JANAF data[2] this yields $\Delta_f H°(298.15\ K) = 88.6 \pm 3.9\ kcal\cdot mol^{-1}$. Trevedi[3] studied the absorption spectrum of FeS and determined $D_0° = 93\ kcal\cdot mol^{-1}$ from the onset of continuous absorption due to photodissociation. This value is likely to be too high in view of the experimental difficulties in determining the exact position of the onset of continuous absorption. Complications arise because of background emission from the furnace. Marquardt and Berkowitz[4] determined an upper limit $D_0° < 77\ kcal\cdot mol^{-1}$ by mass-spectrometric meaurements. These results may be biased since they used $\nu = 412\ cm^{-1}$ for the vibrational frequency of FeS in determining their Gibbs energy functions. A Birge–Sponer extrapolation of the vibrational data to determine $D_0°$ is not meaningful since DeVore and Franzen[5] used the reverse procedure to arrive at the reported value of $\omega_e x_e$.

Heat Capacity and Entropy

With the exception of the observance of one excited state at 17992 cm^{-1} with a vibrational spacing of ~497 cm^{-1} by DeVore and Franzen,[5] there is no information on the electronic spectrum of FeS(g). The identity and quantum weight of this state, as well as the ground state, are unknown. As a result, the electronic states are estimated to be identical to those of the Fe^{2+} ion[6] following the procedure of Brewer and Rosenblatt[7] for the transition metal oxides. As stated by Brewer and Rosenblatt,[7] this procedure usually overestimates the contribution of electronic states. Nevertheless; it appears to be the best method available. The uncertainty assigned to $S°(298.15\ K)$ is based mainly on the uncertainties in this approximation since the presence of the sulfide ion will undoubtedly alter the electronic structure of the iron ion. Levels above 50,000 cm^{-1} are not included since they have a negligible effect on the thermodynamic properties. The vibrational constants are taken from a study of the matrix isolation spectrum by DeVore and Franzen.[5] The rotational constants are estimated based on an oxide–sulfide correlation due to Barrow and Cousins,[8] r(FeS) = 0.237 ± 1.116 r(FeO). The value r(FeO) = 1.626 Å is taken from Suchard.[9] The value of α_e is estimated assuming a Morse potential function using the expression given by Herzberg.[10]

PREVIOUS: September 1977 (1 atm) CURRENT: September 1977 (1 bar)

$S°(298.15\ K) = 53.865 \pm 0.13\ J \cdot K^{-1} \cdot mol^{-1}$

$\Delta_f H°(0\ K) = -163.78 \pm 2.1\ kJ \cdot mol^{-1}$

$\Delta_f H°(298.15\ K) = -167.36 \pm 2.1\ kJ \cdot mol^{-1}$

Enthalpy of Formation

Based on highly accurate adiabatic–shield calorimetry measurements, Gronvold and Westrum[1] reported that the enthalpy of transformation of marcasite to pyrite is -1.05 ± 0.05 kcal·mol^{-1} at 700 K. The adopted value of $\Delta_f H°(298.15\ K)$ is selected to reproduce this enthalpy of reaction within the reported uncertainty. Lipin *et al.*[2] based on combustion calorimetry, reported a value of -5.6 kcal·mol^{-1} for the marcasite pyrite transformation at 298.15 K. Due to the state of the art in combustion calorimetry at the time of this measurement and uncertainty in the products (oxides of sulfur), this value must have a high uncertainty and is given no weight in our selection process.

Heat Capacity and Entropy

The adopted heat capacities of marcasite are based on our analysis of the $C_p°$ measurements (6–700 K) of Gronvold and Westrum.[1] Values above 700 K are extrapolated assuming $C_p°$(marcasite) + 0.075 cal·K^{-1}·mol^{-1}.

The adopted value of $S°(298.15\ K)$ is obtained from the appropriate integration of the adopted $C_p°$ data assuming $S°(6.06\ K) = 0.0008$ cal·K^{-1}·mol^{-1}.

Phase Data

Marcasite has an orthorhombic structure, V_h^{12} = Pnmm, and exists as stoichiometric FeS_2 within the limits of experimental error.[3] Marcasite is known to be metastable with respect to the other known FeS_2 polymorph, cubic pyrite, above 673 K[3] the JANAF Thermochemical Tables[4] indicate it will also be metastable below 673 K. The marcasite to pyrite transformation is kinetically slow at low temperatures and this accounts for the persistence of marcasite in nature. Kjekshus and Rakke[5] found no conversion to pyrite using heat treatments at 573 K for periods up to 14 months. At 673 K the conversion to pyrite is complete in 4 months and is even more rapid (< 1 hour) at 973 K[5]. Indications are that the conversion to pyrite will be complete before the pyrite decomposition temperature of 1016 K is reached.[3]

$S°(298.15\ K) = 52.916 \pm 0.13\ J \cdot K^{-1} \cdot mol^{-1}$

$\Delta_f H°(0\ K) = -167.86 \pm 2.1\ kJ \cdot mol^{-1}$

$\Delta_f H°(298.15\ K) = -171.54 \pm 2.1\ kJ \cdot mol^{-1}$

Enthalpy of Formation

The adopted value of $\Delta_f H°(298.15\ K) = -41.0 \pm 0.5\ kcal \cdot mol^{-1}$ is based on our 3rd law analysis of the equilibrium data of Toulmin and Barton.[1] These authors made corrections for the changing stoichiometry of pyrrhotite as a function of temperature in the pyrrhotite–pyrite equilibrium, and also accounted for the changing activity of pyrrhotite as a function of temperature and stoichiometry. These corrections have not been applied to our analysis of the rest of the equilibrium data shown below.

Source	Method	Reaction*	T/K	Data Points	$\Delta_r H°(298.15\ K)$, kcal·mol^{-1} 2nd law	3rd law	Drift cal·K^{-1}·mol^{-1}	$\Delta_f H°(298.15\ K)$ kcal·mol^{-1}
Toulmin[1]	Electrum–tarnish	A	598– 1016	17**	−71.77 ± 0.12	71.89 ± 0.16	−0.15 ± 0.15	41.0 ± 0.5

**Point at 1009 K rejected by statistical test.

*Reaction: (A) $Fe(cr) + S_2(g) \rightarrow FeS_2$(cr, pyrite)

(B) $1.14\ Fe_{0.877}S(cr) + 0.43\ S_2(g) \rightarrow FeS_2$(cr, pyrite)

(C) $Fe(cr) + 2\ S(cr) \rightarrow FeS_2$(cr, pyrite).

The value reported by DeRanter[4] is biased since FeS_2 is a semiconductor and DeRanter acknowledged that semiconductors lead to incorrect results in his emf technique. The other values are believed to be biased because the equilibrium is treated as if the composition ($Fe_{0.877}S$) and activity (a=1) of pyrrhotite remain unchanged.

Heat Capacity and Entropy

The adopted values of $C_p°$ are based on our analysis of the calorimetrically measured values of Gronvold and Westrum, 4–346 K[7] and 314–688 K.[8] At higher temperatures the $C_p°$ values are based on our analysis of the enthalpy data of Coughlin,[9] 405–980 K, which merges smoothly with the $C_p°$ data of Gronvold and Westrum. Values above 980 K are extrapolated.

The adopted value of $S°(298.15\ K)$ is obtained from the appropriate integration of the adopted $C_p°$ data assuming $S°(4.6\ K) = 0.0007\ cal \cdot K^{-1} \cdot mol^{-1}$.

Phase Data

Pyrite has a cubic structure, T_h^6 = Pa3, and exits as stoichiometric FeS_2 within the limits of experimental error.[10] The other known FeS_2 polymorph is orthorhombic marcasite which is known to be metastable with respect to pyrite above 673 K[10] the JANAF Thermochemical Tables[11] indicate that pyrite will also be the stable form below 673 K.

Decomposition Data

Pyrite melts incongruently to pyrrhotite, a liquid whose composition is ~FeS_4[3] and vapor at 1016 ± 2 K at the vapor pressure of the system, 10 atm.[3,10] Assuming the vapor to be composed only of $S_2(g)$, we calculate[11] a decomposition temperature of 906 K at 1 atm for the process $2.3263\ FeS_2$(pyrite) $\rightarrow S_2(g) + 2.6525\ Fe_{0.87}S$(cr).

Enthalpy of Formation

The chemical equilibrium of the interaction of Fe(cr) and I(g) has been studied by a transpiration method by Zaugg and Gregory.[1] Using the reported equilibrium constants in the temperature range from 591 to 751 K, the enthalpy change $\Delta_f H°(298.15\ K)$ of the reaction 2Fe(cr) + 4I(g) = $Fe_2I_4(g)$ was evaluated by both the 2nd and 3rd law method to be −85.3 and −103.75 $kcal·mol^{-1}$, respectively. The corresponding values of the enthalpy of formation, $\Delta_f H°(Fe_2I_4, g, 298.15\ K)$, are calculated as +16.9 and −1.6 $kcal·mol^{-1}$. Mass spectrometric and Knudsen effusion techniques have been used to study the vaporization of $FeI_2(cr)$ by Schoonmaker *et al.*[2] Using the reported vapor pressure, $p = 1.21 \times 10^{-6}$ atm at 714 K for $Fe_2I_4(g)$, the enthalpy change $\Delta_r H°(298.15\ K)$ for the reaction $2FeI_2(cr) = Fe_2I_4(g)$ was evaluated by the 3rd law method as 52.8 $kcal·mol^{-1}$, yielding $\Delta_f H°(298.15\ K)$ = 2.8 $kcal·mol^{-1}$ for $Fe_2I_4(g)$.

The adopted value of $\Delta_f H°(298.15\ K)$ for $Fe_2I_4(g)$ is 2.0 ± 5 $kcal·mol^{-1}$ (8.368 ± 20.9 $kJ·mol^{-1}$).

Heat Capacity and Entropy

The molecular structure was assumed to be the same as that for $Fe_2Br_4(g)$. The Fe–I bond distance was estimated from that in $FeI_2(g)$ molecule. Four vibrational frequencies (ν_i), i.e. i = 2, 4, 5 and 6, were estimated by comparison with those for $K_2I_2(g)$, calculated by Berkowitz.[3] The other frequency values were estimated from those for $FeI_2(g)$. The electronic levels and quantum weights were estimated from those for $FeI_2(g)$. The principal moments of inertia are: $I_A = 124.4358 \times 10^{-39}$, $I_B = 780.0258 \times 10^{-39}$, and $I_C = 904.4616 \times 10^{-39}$ $g·cm^2$.

PREVIOUS: September 1966 (1 atm) CURRENT: September 1966 (1 bar)

Iron Oxide, Hematite (Fe_2O_3) CRYSTAL M_r = 159.6922

$S°(298.15\ K) = 87.400\ J·K^{-1}·mol^{-1}$

$\Delta_f H°(0\ K) = -819.03 \pm 1.3\ kJ·mol^{-1}$

$\Delta_f H°(298.15\ K) = -825.50 \pm 1.3\ kJ·mol^{-1}$

Enthalpy of Formation

The chemical equilibria for the reaction 4 Fe_3O_4(cr) + O_2(g) = 6 Fe_2O_3(cr) have been studied by several investigators. From the reported data the corresponding values of $\Delta_r H°(298.15\ K)$ and $\Delta_f H°(Fe_2O_3, cr, 298.15\ K)$ were evaluated. The results obtained are given as follows:

Source	T/K	$\Delta_r H°(298.15\ K)$, kcal·mol^{-1} 2nd law	3rd law	$\Delta_f H°(298.15\ K)$ kcal·mol^{-1}
Tretyakov and Khomyakov[1]	1373–1728	−106.32 ± 0.19	−111.05	−197.11
Schmahl[2]	1583–1683	−123.95 ± 1.37	−112.94	−197.42
Smiltens[3]	1373–1673	−117.88 ± 0.38	−114.25	−197.64
Darken and Gurry[4]	1723	−110.29		196.98

The value of $\Delta_f H°(298.15\ K)$ adopted for Fe_2O_3(cr) is the weighted average of the $\Delta_f H°(298.15\ K)$ values listed in the above table.

Heat Capacity and Entropy

The low temperature (5.58–345.42 K) heat capacities were determined by Gronvold and Westrum).[5] The high temperature (298–1750 K) $C_p°$ values were obtained from Coughlin *et al.*[6] The two sets of data were plotted and joined smoothly at 298 K. The $C_p°$ values above 1750 K were obtained by graphical extrapolation. The heat capacities of Fe_2O_3(cr) have also been reported by Brown and Furnas (0–650 °C),[7] and Parks and Kelley (88 289 K).[8] $S°(298.15\ K)$ for Fe_2O_3(cr) was derived from the smoothed $C_p°$ data, based on $S°(5\ K) = 0.0003\ calK^{-1}·mol^{-1}$. Coughlin *et al.*[6] measured the enthalpy for hematite and found two anomalies, presumably of megnetic nature, at about 950 and 1050 K, respectively. Both appear to involve maxima in the heat capacity curves rather than isothermal heats of transformation. The complex magnetic properties at low temperatures were discussed by Gronvold and Westrum.[5] No heat capacity anomaly was observed at the magnetic transition about 250 K. The Curie points of the antiferromagnetic α Fe_2O_3 were reported by Aharoni *et al.*[9] and Lielmezs and Chaklader.[10]

Decomposition Data

T_{dcm} = 1735 K is the temperature at which the pressure is 1 atm for the reaction 6 Fe_2O_3(cr) = 4 Fe_3O_4(cr) + O_2(g). In other words, Fe_2O_3(cr) decomposes into Fe_3O_4(cr) and O_2(g) at 1735 K.

PREVIOUS: CURRENT: June 1965

$S°(298.15\ K) = [307.524 \pm 8.4]\ J \cdot K^{-1} \cdot mol^{-1}$

$\Delta_f H°(0\ K)$ = Unknown

$\Delta_f H°(298.15\ K) = -2582.99 \pm 1.67\ kJ \cdot mol^{-1}$

Enthalpy of Formation

The enthalpy change, $\Delta_r H°(298.15\ K)$, for the chemical reaction $Fe_2O_3(cr) + 3(H_2SO_4 \cdot 14.855\ H_2O)(sol.) = Fe_2(SO_4)_3(cr) + 47.565\ H_2O(l)$ was measured to be $8.54 + 0.18\ kcal \cdot mol^{-1}$ by solution calorimetry by Barany and Adami.[1] Using $\Delta_f H°(298.15\ K) = -211.178\ kcal \cdot mol^{-1}$ for $H_2SO_4 \cdot 14.855\ H_2O$(sol.) and $-68.315\ kcal \cdot mol^{-1}$ for H_2O(l), obtained from and $-197.3\ kcal \cdot mol^{-1}$ for Fe_2O_3(cr), the enthalpy of formation, $\Delta_f H°(298.15\ K)$, for $Fe_2(SO_4)_3$(cr) was evaluated as $-617.35 \pm 0.40\ kcal \cdot mol^{-1}$ which was adopted here.

The equilibrium pressures for the decomposition of $Fe_2(SO_4)_3$(cr) have been determined by several investigators at different temperatures. The chemical reactions are: (1) $Fe_2(SO_4)_3(cr) = Fe_2O_3(cr) + 3\ SO_3(g)$ and (2) $SO_3(g) = SO_2(g) + 0.5\ O_2(g)$. However, the measured pressure of the chemical equilibrium is the total pressure of three partial pressures, namely, $P(SO_3)$, $P(SO_2)$, and $P(O_2)$. In order to calculate the enthalpy change of Reaction (1), the partial pressures of SO_3(g) were evaluated from the total vapor pressure data at each temperature. Based on the derived values for $P(SO_3)$, the $\Delta_r H°(298.15\ K)$ value for Reaction (1) was calculated by both the 2nd and 3rd law methods. The results obtained are presented in the following table. The $\Delta_f H°(Fe_2(SO_4)_3$, cr, 298.15 K) values were derived, using the 3rd law $\Delta_r H°(298.15\ K)$. These determinations were not given any weight.

Wohler and Grunzweig[6]	909.15– 994.15	155.1 ± 1.3	135.5 ± 1.3	−20.4 ± 1.4	−616.6
Neumann and Heintke[7]	793.15– 973.15	136.4 ± 2.3	136.2 ± 1.2	−1.2 ± 2.6	−617.3
Warner and Ingraham[8]	903.15– 997.15	133.9 ± 2.6	135.4 ± 0.5	1.7 ± 2.7	−616.5

The decomposition pressures of $Fe_2(SO_4)_3$(cr) have also been investigated by: Grunzweig (793–994 K),[9] Blanks (845–976 K),[10] and Ingraham (856–995 K).[11] These data together with some of the data mentioned previously were critically reviewed by Kellogg.[12]

Heat Capacity and Entropy

The heat capacities were estimated by comparison with those for $FeSO_4$(cr), assuming their average specific heats, $cal \cdot K^{-1} \cdot g^{-1}$, to be the same. The value of $S°(298.15\ K)$ was estimated so that the 2nd and 3rd law $\Delta_r H°(298.15\ K)$ values, derived from decomposition pressure data, are in reasonable agreement.

Decomposition Data

T_{dcm} is the temperature (1451 K) at which the total pressure of the gaseous products equals one atmosphere, which was obtained by graphical extrapolation of the decomposition pressure data measured by Warner and Ingraham.[8]

$S°(298.15\ K) = 145.266\ J·K^{-1}·mol^{-1}$
$T_{fus} = 1870 \pm 2\ K$

$\Delta_f H°(0\ K) = -1114.58 \pm 0.8\ kJ·mol^{-1}$
$\Delta_f H°(298.15\ K) = -1120.89 \pm 0.8\ kJ·mol^{-1}$
$\Delta_{fus} H° = 138.070 \pm 8.4\ kJ·mol^{-1}$

Enthalpy of Formation

The equilibrium constants for the following four reactions, i.e. (A) $3Fe(cr) + 4H_2O(g) = Fe_3O_4(cr) + 4H_2(g)$; (B) $Fe_3O_4(cr) + H_2(g) = 3FeO(cr) + H_2O(g)$; (C) $Fe_3O_4(cr) + CO(g) = 3FeO(cr) + CO_2(g)$; and (D) $2Fe_3O_4(cr) = 6FeO(cr) + O_2(g)$, have been studied by several investigators. Using their reported equilibrium data, the corresponding enthalpy changes, $\Delta_r H°(298.15\ K)$, were evaluated by both 2nd and 3rd law methods. Based on the 3rd law value for $\Delta_r H°(298.15\ K)$, the respective $\Delta_f H°(298.15\ K)$ values for $Fe_3O_4(cr)$ were also derived. The results obtained are presented as follows.

Source	Reactions	T/K	$\Delta_r H°(298.15\ K)$, kcal·mol^{-1} 2nd law	3rd law	$\Delta_f H°(298.15\ K)$ kcal·mol^{-1}

The enthalpy change of the reaction $Fe_{0.947}0(cr) + 0.8215\ Fe(cr) + 0.6787\ O_2(g) = 0.5895\ Fe_3O_4(cr)$ has been determined by Humphrey *et al.*[6] Based on $\Delta_r H°(298.15\ K) = -93.46\ kcal·mol^{-1}$ (average of two separate values derived from two experimental determinations) and $\Delta_f H°(wustite, cr, 298.15\ K) = -63.64\ kcal·mol^{-1}$, the value $\Delta_f H°(Fe_3O_4, cr, 298.15\ K)$ was calculated as $-266.5\ kcal·mol^{-1}$. The enthalpy change, $\Delta_r H°(298.15\ K) = 4.33\ kcal·mol^{-1}$, for the reaction $3Fe(cr) + 4CO_2(g) = Fe_3O_4(cr) + 4CO(g)$ was reported by Darken and Gurry.[7] The corresponding $\Delta_f H°(Fe_3O_4, cr, 298.15\ K)$ was evaluated as $-266.22\ kcal·mol^{-1}$. The adopted value of $\Delta_f H°(298.15\ K)$ for $Fe_3O_4(cr)$ is selected as $-267.9 \pm 0.2\ kcal·mol^{-1}$.

Heat Capacity and Entropy

The low temperature heat capacities (60.5–299.7 K) were reported by Millar.[8] The high temperature heat capacities (298–1800 K) were obtained from Coughlin *et al.*[9] These two sets of data were plotted and joined smoothly at 298.15 K. The $C_P°$ values above 1800 K were obtained by graphical extrapolation. Heat capacities (90–295 K) for $Fe_3O_4(cr)$ were also reported by Parks and Kelley.[10] $S°(Fe_3O_4, cr, 298.15\ K)$ was derived from the smoothed $C_p°$ data mentioned previously, using $S°(44.7\ K) = 0.969\ cal·K^{-1}·mol^{-1}$. Coughlin *et al.*[9] measured the heat–content for magnetite and found a magnetic anomaly around 880 K, corresponding to a maximum in heat capacity. A maximum heat capacity of 37.1 $cal·K^{-1}·mol^{-1}$ at 114.15 K was also reported by Millar.[8]

Fusion Data

T_{fus} and $\Delta_{fus}H°$ were obtained from Darken and Gurry.[7]

$S°(298.15\ K) = 40.838 \pm 0.20\ J \cdot K^{-1} \cdot mol^{-1}$
$T_{fus} = 302.92 \pm 0.02\ K$

$\Delta_f H°(0\ K) = 0\ kJ \cdot mol^{-1}$
$\Delta_f H°(298.15\ K) = 0\ kJ \cdot mol^{-1}$
$\Delta_{fus} H° = 5.59 \pm 0.04\ kJ \cdot mol^{-1}$

Enthalpy of Formation

Zero by definition.

Heat Capacity and Entropy

The adopted thermal functions are those recommended by Hultgren *et al.*[1] The heat capacity values were based on the studies of Phillips (0.1–4.2 K),[2] Seidel and Kiesom (0.35–4.38 K),[3] Eichenaur and Schulze (5–22 K),[4] Adams *et al.* (15–323 K),[5] and Clusius and Hartick (15–200 K).[6] Refer to Hultgren *et al.*[1] for details.

Enthalpy of Fusion

Refer to the liquid table for details.

Enthalpy of Sublimation

The enthalpy of sublimation is the enthalpy of formation of the gas, $\Delta_{sub} H°(298.15\ K) = \Delta_f H°(g, 298.15\ K)$.

PREVIOUS: CURRENT: June 1983

$S°(298.15\ K) = [59.253]\ J·K^{-1}·mol^{-1}$
$T = 302.92 \pm 0.02\ K$

$\Delta_f H°(298.15\ K) = [5.578]\ kJ·mol^{-1}$
$\Delta_{fus} H° = 5.59 \pm 0.04\ kJ·mol^{-1}$

Enthalpy of Formation

The enthalpy of formation, $\Delta_f H°$(l, 298.15 K), is calculated from that of the crystal by adding the enthalpy of fusion and the difference in enthalpy, $H°(302.92\ K) - H°(298.15\ K)$, between the crystal and liquid.

Heat Capacity and Entropy

The heat capacity of the liquid is based on the recommendations of Hultgren *et al.*[1] These values are based on the enthalpy data of Kochethova and Rezukhina (315–712 K),[2] and the heat capacity data of Chen and Turnbull (245–611 K).[3]

Enthalpy of Fusion

The adopted value for the enthalpy of fusion is derived from the direct calorimetric measurement of Roth *et al.*[4]

The temperature of fusion, $T_{fus} = 302.92 \pm 0.2$ K (corrected to IPTS–68), was derived from the study of Boedtker *et al.*[5]

Enthalpy of Vaporization

The temperature at which $\Delta_f G° = 0$ (1 bar) for the process Ga(l) → Ga(g) is the adopted T_{vap} (1bar). The difference in the enthalpies of formation of the ideal gas and liquid at T_{vap} is $\Delta_{vap} H°$. Refer to the ideal gas table for additional information.

Enthalpy of Formation

The enthalpy of formation of Ga(g), as recommended by Hultgren *et al.*,[1] was derived from the third law analysis of seven vaporization studies and a spectroscopic calculation. The studies are: Matern *et al.* (1081–1213 K),[2] Macur *et al.* (1196–1473 K),[3] Alcock *et al.* (1173–1437 K),[4] Munir and Searcy (1174–1603 K),[5] Cochran and Foster (1179–1383 K),[6] Speiser and Johnston (1230–1518 K),[7] Hartick (1198–1391 K),[8] and the spectroscopic calculaion by Gurvich.[9]

Heat Capacity and Entropy

The thermal functions were calculated using the atomic levels as given by Moore.[10] The resulting thermal functions are those recommended by Hultgren *et al.*[1]

$^3P_1$	47816	3
$^3P_2$	48750	5

Enthalpy of Formation

$\Delta_f H°(Ga^+, g, 0 K)$ is calculated from $\Delta_f H°$(Ga, g, 0 K)[1] using the spectroscopic value of IP(Ga) = 48387.63 ± 0.1 cm^{-1}(578.837 ± 0.001 $kJ·mol^{-1}$) from Moore.[2] The ionization limit is converted from cm^{-1} to $kJ·mol^{-1}$ using the factor, 1 cm^{-1} = 0.01196266 $kJ·mol^{-1}$, which is derived from the 1973 CODATA fundamental constants.[3] Rosenstock *et al.*[4] and Levin and Lias[5] have summarized additional ionization and appearance potential data.

$\Delta_f H°(Ga^+, g, 298.15 K)$ is calculated from $\Delta_f H°$(Ga, g, 0 K) by using IP(Ga) with JANAF[1] enthalpies, $H°(0 K)-H°(298.15 K)$, for Ga(g), Ga^+(g), and e^-(ref). $\Delta_f H°(Ga \rightarrow Ga^+ + e^-, 298.15 K)$ differs from a room temperature threshold energy due to inclusion of these enthalpies and to threshold effects discussed by Rosenstock *et al.*[4] $\Delta_f H°$(298.15 K) should be changed by −6.197 $kJ·mol^{-1}$ if it is to be used in the ion convention that excludes the enthalpy of the electron.

Heat Capacity and Entropy

The information on electronic energy levels and quantum weights, given by Moore,[2,6] is incomplete because many theoretically predicted levels have not been observed. Our calcualtions indicate that any reasonable method of filling in these missing levels and cutting off the summation in the partition function[7] has no effect on the thermodynamic functions to 6000 K. This is a result of the high energy of all levels other than the ground state and the first three excited states; the next excited state is 70700 cm^{-1} above the ground state. Since inclusion of these excited states has no effect on the thermodynamic functions (to 6000 K), we list only the ground state and the first three excited states. The position of the $^3P_0$ levels are uncertain by 249 cm^{-1}. The reported uncertainty in $S°$(298.15 K) is due to uncertainties in the relative ionic mass and the fundamental constants. Extension of these calculations above 6000 K may require consideration of the excited states and use of different fill and cutoff procedures.[7]

Enthalpy of Formation

$\Delta_f H°(Ga^-, g, 0\ K)$ is calculated from $\Delta_f H°(Ga, g, 0\ K)$[1] using the adopted electron affinity of EA(Ga) = 0.30 ± 0.15 eV (28.945 ± 14.473 $kJ·mol^{-1}$). This value, recommended by Hotop and Lineberger,[2] is based on a photodetachment threshold (using conventional light sources) and semiempirical extrapolation.[3, 4, 5] Additional information on $Ga^-(g)$ may be obtained in the critical discussions of Hotop and Lineberger,[2,5] Rosenstock *et al.*[6] and Massey.[7]

$\Delta_f H°(Ga^-, g, 298.15\ K)$ is obtained from $\Delta_f H°(Ga, g, 0\ K)$ by using EA(Ga) with JANAF[1] enthalpies, $H°(0\ K)$–$H°(298.15\ K)$, for $Ga^-(g)$, Ga(g), and e^-(ref). $\Delta_r H°(Ga^- \rightarrow Ga + e^-, 298.15\ K)$ differs from a room–temperature threshold energy due to inclusion of these enthalpies and to threshold effects discussed by Rosenstock *et al.*[6] $\Delta_f H°(298.15\ K)$ should be changed by +6.197 $kJ·mol^{-1}$ if it is to be used in the ion convention that excludes the enthalpy of the electron.

Heat Capacity and Entropy

The ground state electronic configuration for $Ga^-(g)$ is given by Hotop and Lineberger,[2, 5] Rosenstocsk *et al.*,[6] and Massey.[7] The fine–structure separation has been calculated via an isoelectronic extrapolation of ratios of fine structure separations and a quadratic isoelectronic extrapolation[4, 5] and is that recommended by Hotop and Lineberger.[2]

A comparison of the isoelectronic sequences – $Ga^-(g)$, Ge(g), $As^+(g)$, $Se^{++}(g)$ – would suggest that a state, $^1D_2$, may exist at low wave numbers. However, this is most likely a metasable state lying at an energy greater than the electron affinity, as in the case of $Al^-(g)$. As discussed by Hotop and Lineberger,[2, 5] Rosenstock *et al.*,[6] and Massey,[7] no stable excited states have been observed. Thus, we assume no stable excited states exist.

Enthalpy of Formation

The enthalpy of formation is calculated from the dissociation energy, $D_0°(H_2) = 36118.3 \pm 1\ cm^{-1}$ ($432.071 \pm 0.012\ kJ·mol^{-1}$), from Herzberg[2] and auxiliary data from H_2.[3] The adopted value for the dissociation energy of hydrogen is the value recommended by CODATA.[1]

Earlier experimental values for $D_0°(H_2)$ were obtained by Herzberg and Monfils (36113.0 ± 0.3 cm^{-1}),[4] and Beutler (36116 ± 6 cm^{-1}).[5] Kolos and Wolniewicz[6] calculated the adiabatic dissociation energy of H_2, corrected for relativistic and radiative effects, to be 36117.4 cm^{-1}.

Heat Capacity and Entropy

The electronic levels for H(g) are given in the compilation by Moore.[7] Our calculations indicate that the inclusion of levels through $n = 12$ has no effect on the thermodynamic functions to 6000 K. This is a result of the high energy of these levels; the first excited state lies at 82258 cm^{-1} above the ground state. Since the inclusion of these upper levels has no effect on the thermodynamic functions (to 6000 K) we list only the ground state. The reported uncertainty in $S°(298.15\ K)$ is due to uncertainties in the relative atomic mass and the fundamental constants. Extension of these calculations above 6000 K may require consideration of the higher excited states and utilization of proper fill and cut off procedures.[8]

The thermal functions at 298.15 K differ from the CODATA recommendations for two reasons: a difference of 0.001 $J·K^{-1}·mol^{-1}$ in the entropy due to the use of more current fundamental constants and a difference of 0.1094 $J·K^{-1}·mol^{-1}$ in the entropy due to the use of a different standard state pressure.

PREVIOUS: March 1977 (1 atm) CURRENT: March 1982 (1 bar)

$S°(298.15\ K) = 108.946 \pm 0.02\ J\ K^{-1}\cdot mol^{-1}$

$\Delta_f H°(0\ K) = 1528.085 \pm 0.04\ kJ\cdot mol^{-1}$

$\Delta_f H°(298.15\ K) = [1536.246]\ kJ\cdot mol^{-1}$

Enthalpy of Formation

$\Delta_f H°(H^+, g, 0\ K)$ is calculated from $\Delta_f H°(H, g, 0\ K)$[1] using the spectroscopic value of IP(H) = 109678.764 ± 0.005 cm^{-1} (1312.0498 ± 0.0001 $kJ\cdot mol^{-1}$) from Moore.[2] The ionization limit is converted from cm^{-1} to $kJ\cdot mol^{-1}$ using the factor, 1 cm^{-1} = 0.01196266 $kJ\cdot mol^{-1}$, which is derived from the 1973 CODATA fundamental constants[3]. Rosenstock *et al.*[4] and Levin and Lias[5] have summarized additional ionization and appearance potential data.

$\Delta_f H°(H^+, g, 298.15\ K)$ is calculated from $\Delta_f H°(H, g, 0\ K)$ by using IP(H) with JANAF[1] enthalpies, $H°(0\ K)-H°(298.15\ K)$, for H(g), H^+(g), and e^-(ref). $\Delta_f H°(H \rightarrow H^+ + e^-, 298.15\ K)$ differs from a room temperature threshold energy due to inclusion of these enthalpies and to threshold effects discussed by Rosenstock *et al.*[4] $\Delta_f H°(298.15\ K)$ should be changed by −6.197 $kJ\cdot mol^{-1}$ if it is to be used in the ion convention that excludes the enthalpy of the electron.

Heat Capacity and Entropy

The thermodynamic functions of the proton gas are calculated using the recent CODATA fundamental constants[2] and assuming that the proton is an ideal monatomic gas. Since there is no electron associated with this species, there is only a translational contribution to the thermochemical function.

Enthalpy of Formation

$\Delta_f H°(H^-, g, 0 K)$ is calculated from $\Delta_f H°(H, g, 0 K)$[1] using the adopted electron affinity of EA(H) = 0.754209 ± 0.000003 eV (72.7695 ± 0.0003 kJ·mol^{-1}). This value, recommended by Hotop and Lineberger,[2] is based on extensive Hylleras–type variational calculations on two election systems.[3,4,5] Additional information on H^-(g) may be obtained in the critical discussions of Hotop and Lineberger,[2, 6] Rosenstock *et al.*[7] and Massey.[8] Experimentally, Dehmer and Chupka[9] have reported EA(H) ≥0.7540 ± 0.0003 eV.

$\Delta_f H°(H^-, g, 298.15 K)$ is obtained from $\Delta_f H°(H, g, 0 K)$ by using EA(H) with JANAF[1] enthalpies, $H°(0 K)–H°(298.15 K)$, for H^-(g), H(g), and e^-(ref). $\Delta_r H°(H^- \rightarrow H + e^-, 298.15 K)$ differs from a room–temperature threshold energy due to inclusion of these enthalpies and to threshold effects discussed by Rosenstock et al.[7] $\Delta_f H°$(298.15 K) should be changed by +6.197 kJ·mol^{-1} if it is to be used in the ion convention that excludes the enthalpy of the electron.

Heat Capacity and Entropy

The ground state electronic configuration for H^-(g) is given by Hotop and Lineberger[2, 6] and Rosenstock *et al.*[7] A comparison of the isoelectronic sequence – H^-(g), He(g), Li^+(g) – would suggest that stable electronic states may exist at 0.8 EA(H) or roughly 6400 cm^{-1}. This would greatly affect the entropy. However, Pekeris[4] states that he was unable to find any bound states. In addition, Seman and Branscomb[10] state that theoretical and semiempirical evidence suggests that atomic negative ions have very few if any excited states below the continuum. We assume no stable excited states exist.

PREVIOUS: June 1963 (1 atm) CURRENT: June 1963 (1 bar)

$S°(298.15\ K) = 206.589\ J·K^{-1}·mol^{-1}$

$\Delta_f H°(0\ K) = 28.535 \pm 0.21\ kJ·mol^{-1}$
$\Delta_f H°(298.15\ K) = 26.359 \pm 0.21\ kJ·mol^{-1}$

Electronic Level and Quantum Weight		
State	ϵ_i, cm^{-1}	g_i
$^1\Sigma$	0	1

$\omega_e = 2309.06\ cm^{-1}$ $\omega_e x_e = 39.73\ cm^{-1}$ $\sigma = 2$
$B_e = 6.512\ cm^{-1}$ $\alpha_e = 0.1715\ cm^{-1}$

Enthalpy of Formation

Using the calculated thermal functions and functions for H_2(g) and I_2(g) given in the JANAF tables, equilibrium data from the literature are used to calculate $\Delta_f H°(298.15\ K)$ for the reaction $H_2(g) + I_2(g) \rightarrow 2\ HI(g)$.

Source	$\Delta H°(298.15\ K)$, $kcal·mol^{-1}$
Taylor and Crist[4] (667 to 764 K)	−2.375 ± .005
Bodenstin[5] (556 to 781 K)	−2.053 ± .133
Bright and Hagerty[6] (696 and 779 K)	−2.219 ± .070
Rittenberg and Urey[7] (671 and 741 K)	−2.156 ± .072

The data of Taylor and Crist are the most concordant and are given the most weight. Converting to the solid state of iodine, which has been adopted as a JANAF reference state gives the standard enthalpy of formation of hydrogen iodide.

Heat Capacity and Entropy

Molecular constants are from Cowan and Gordy[1] and Boyd and Thompson.[2] The calculated functions are in reasonable agreement with the compilation of Kelley.[3]

Bond Angles: H–Si–I = [106.81]° I–Si–I = [112]°

Product of the Moments of Inertia: $I_A I_B I_C = [1.04795 \times 10^{-110}]\ g^3 \cdot cm^6$

Enthalpy of Formation

$\Delta_f H°(298.15\ K)$ is estimated by linear interpolation between the values[1] of $SiI_4(g)$ and $SiH_4(g)$. There are no experimental $\Delta_f H°$ data for SiH_3I, SiH_2I_2, and $SiHI_3$. Data for the iodomethanes[2] have a surprising progression, (SiH_3I, g);[1] they are of doubtful use in predicting $\Delta_f H°$ of the iodosilanes. We conclude, as did Hunt and Sirtl,[3] that the available data justify only linear interpolation.

Heat Capacity and Entropy

The molecular structure is estimated by comparison with SiH_3I, SiI_4 and the various bormo–, chloro–, and fluorosilanes.[1] The principal moments of inertia are: $I_A = I_B = 174.6 \times 10^{-39}$ and $I_C = 343.48 \times 10^{-39}\ g \cdot cm^2$.

Vibrational frequencies are from liquid–phase Raman spectra of Hengge and Hoefler.[4] Infrared data, also presumably for the liquid phase, were reported[4] for ν_1 and ν_4.

We neglect excited states and assume the electronic ground state to be a singlet. We expect that contributions from excited states should be unimportant, as discussed on the tables for SiH_3Br and SiH_2Cl_2.[1]

PREVIOUS: December 1976 (1 atm) CURRENT: December 1976 (1 bar)

$\Delta_f H°(0\ K)$ = Unknown

$S°(298.15\ K)$ = [50.208] $J·K^{-1}·mol^{-1}$ $\Delta_f H°(298.15\ K)$ = −57.820 ± 0.046 $kJ·mol^{-1}$

Enthalpy of Formation

The value of $\Delta_f H°(298.15\ K)$ is taken from Gunn and Green.[1] The corresponding value reported by Messer *et al.*[2] was −15.16 ± 0.6 $kcal·mol^{-1}$. In this latter paper, the results of the previous investigations were also reviewed.

Heat Capacity and Entropy

$C_p°$ and $S°(298.15\ K)$ are estimated by comparison with those for NaH(cr) and LiH(cr).

Decomposition Data

T_{dcm} = 690 K was assumed to be the temperature at which the value of $\Delta_f G°$ changes from negative to positive.

$S°(298.15\ K) = 78.907 \pm 0.84\ J \cdot K^{-1} \cdot mol^{-1}$
$T_{trs} = 516\ K$
$T_{fus} = 679\ K$

$\Delta_f H°(0\ K) = -421.22 \pm 0.4\ kJ \cdot mol^{-1}$
$\Delta_f H(298.15\ K) = -424.72 \pm 0.4\ kJ \cdot mol^{-1}$
$\Delta_{trs} H° = 6.443 \pm 0.63\ kJ \cdot mol^{-1}$
$\Delta_{fus} H° = 8.619 \pm 0.63\ kJ \cdot mol^{-1}$

Enthalpy of Formation

The enthalpy of formation of KOH(cr) is obtained from its enthalpy of solution in water, the enthalpy of hydrolysis of metallic potassium, and appropriate auxiliary data.

Reshetnikov[1] determined calorimetrically the enthalpy of solution of KOH(cr) in 650 H_2O as -13.665 ± 0.009 kcal·mol^{-1}. Combining this result with enthalpy of dilution data for KOH reported by Parker[2] we derive $\Delta_{sln}H°(KOH, cr) = -13.77 \pm 0.01$ kcal·mol^{-1}.

The enthalpy of hydrolysis of metallic potassium has been determined by various investigators.[3–5] The data are summarized below for the reaction $K(cr) + (n + 1)H_2O(l) \rightarrow KOH \cdot nH_2O + 0.5\ H_2(g)$.

Source	n moles of H_2O	$\Delta_f H°$(298.15 K) kcal·mol^{-1}	$\Delta_f H°$(KOH, aq, ∞, 298.15 K)* kcal·mol^{-1}	$\Delta_f H°$(KOH, cr, 298.15 K) kcal·mol^{-1}
Gunn and Green[3a,3b]	∞	−46.958 ± 0.22	−115.273 ± 0.22	−101.50 ± 0.02
Messer *et al.*[4]	∞	−47.02 ± 0.15	−115.34 ± 0.15	−101.57 ± 0.16
Ketchen and Wallace[5]	∞	−46.89 ± 0.24	−115.21 ± 0.24	−101.44 ± 0.25

*Based on $\Delta_f H$ (H_2O, l, 298.15 K) = −68.315 kcal·mol^{-1}.[6]

The values of $\Delta_f H°$(KOH, cr, 298.15 K) given in the last column are calculated from $\Delta_f H°$(KOH, aq, ∞, 298.15 K) and the enthalpy of solution of KOH(cr) at infinite dilution given above. The adopted value for $\Delta_f H°$(KOH, cr, 298.15 K) is from the work of Gunn and Green.[3a,3b]

Earlier investigations pertaining to the determination of $\Delta_f H°$(KOH, cr, 298.15 K) have been reviewed by Bichowsky and Rossini[7] and Messer *et al.*[4] and are only of historical interest.

Heat Capacity and Entropy

The low temperature heat capacities for KOH(cr) in the temperature range 20–298 K are from the recent work of Stull *et al.*.[8] These data contain a broad lambda type transition with a heat capacity peak at 227.5 K. Powers and Blalock[9] measured high temperature enthalpy data for KOH(cr) in both the α and β phases in a Bunsen ice calorimeter. Their enthalpy data are scattered and not precise enough to accurately define the heat capacities for the α phase. Therefore, the selected heat capacities between 298 and 516 K are estimated by graphical extrapolation of the low temperature heat capacity data. Heat capacities for the β phase are from Powers and Blalock.[9]

$S°(298.15\ K)$ is calculated from the smoothed C_p^o data and is based on an extrapolation of $S°(20\ K) = 0.199$ cal·K^{-1}·mol^{-1}.

Transition and Fusion Data

Several values for the enthalpy of the α–β transition and the enthalpy of melting of KOH have been reported in the literature.

Source	Method	T_{trs}/K	$\Delta_{trs}H°$ kcal·mol^{-1}	T_{fus}/K	$\Delta_{fus}H°$ kcal·mol^{-1}
Powers and Blalock[9]	Calorimetric	522	1.346	673	2.244
Seward and Martin[10]	Freezing Point			683	1.830
Kelly[11]	Freezing Point			633	1.980
Reshetnikov and Baranskaya[12]	Thermographic	515	1.540 ± 0.5	679	1.980 ± 0.15
Maurice[13]	Freezing Point	517		678	2.13 ± 0.07

The selected values are from the work of Reshetnikov and Baranskaya[12] and Maurice.[13]

Sublimation Data

$\Delta_{sub}H°(298.15\ K)$ for the monomer and dimer are calculated from the selected enthalpies of vaporization and the enthalpy of melting at 298.15 K. See the ideal gas table for details.

PREVIOUS: March 1966 CURRENT: December 1970

$S°(298.15\ K) = [96.617]\ J·K^{-1}·mol^{-1}$ $\Delta_f H°(298.15\ K) = [-412.705]\ kJ·mol^{-1}$

$T_{fus} = 679\ K$ $\Delta_{fus}H° = 8.619 \pm 0.63\ kJ·mol^{-1}$

Enthalpy of Formation

$\Delta_f H°$(KOH, l, 298.15 K) is calculated from that of the crystal by adding $\Delta_{fus}H°$ and the difference in enthalpy, $H°(679\ K) - H°(298.15\ K)$, between the crystal and liquid.

Heat Capacity and Entropy

The heat capacity of the liquid phase is obtained from the high temperature enthalpy measurements of Powers and Blalock[1] The constant $C_p°$ is extrapolated below the melting point and up to 2000 K.

$S°$(298.15 K) is calculated in a manner similar to that used for the enthalpy of formation.

Fusion Data

Refer to the crystal table for details.

Vaporization Data

T_{vap} = 1596 K for the process KOH(l) = KOH(g) is calculated as the temperature at which the fugacity of KOH(g) is 1 atm. The difference in the enthalpies of formation of KOH(l) and KOH(g) at T_{vap} is the enthalpy of vaporization. If $[KOH]_2$(g) is also considered a minor component in the vapor mixture (approximately 2% of the total vapor pressure at the boiling point) the calculated boiling point is unchanged.

Wartenberg and Albrecht[2] reported a boiling point of 1597 K for KOH from static vapor pressure measurements, while very recently Dubois and Millet[3] determined a boiling point of 1540 K from transpiration vapor pressure measurements.

Enthalpy of Formation

Mass spectrometric studies[1-5] of the equilibrium gases over pure KOH(cr, l) and mixed KOH–NaOH condensed phases have unequivocally identified the vapor species as monomer and dimer in the temperature range 600–700 K. Absolute partial pressures for KOH(g) and $K_2(OH)_2$ (g) have been determined from peak intensity data by Porter and Schoonmaker[3] and Gusarov and Gorokhov.[5] These data are analyzed by the 3rd law method with JANAF Gibbs energy functions[6] in order to evaluate an enthalpy of dimerization at 298 K. The adopted value is $\Delta_f H°(298.15\ K) = -45.3 \pm 3.0\ kcal·mol^{-1}$ for the reaction 2 KOH(g) = $K_2(OH)_2$ (g).

Vapor pressures for liquid KOH have been determined by static (1443–1600 K)[7] and transpiration (873–1323 K)[8] methods. In order to evaluate $\Delta_{vap}H°$(KOH, l, 298.15 K) we have used a trial and error variation of $\Delta_{vap}H°(298.15\ K)$ for the monomer and dimer, such that these values are in accordance with the adopted enthalpy of dimerization given above, and the sum of the calculated partial pressures for KOH(g) and $[KOH]_2$(g) is in good agreement with the experimental vapor pressure data. Since the dimer to monomer ratio decreases with increasing temperature, more weight is given to the static data of Wartenberg and Albrecht.[7] The selected values are: $\Delta_{vap}H°$(to monomer, 298.15 K) = 43.0 ± 3.0 $kcal·mol^{-1}$ and $\Delta_{vap}H°$(to dimer, 298.15 K) = 40.8 ± 3.0 $kcal·mol^{-1}$. From these results we derive $\Delta_f H°$(KOH, g, 298.15 K) = −55.6 ± 3.0 $kcal·mol^{-1}$ with $\Delta_f H°$(KOH, l, 298.15 K) = −98.64 ± 0.50 $kcal·mol^{-1}$.[6] This value is adopted here and when used in combination with the enthalpy of dimerization results in $\Delta_f H°[KOH]_2$, g, 298.15 K) = −156.5 ± 3.0 $kcal·mol^{-1}$.

The bond dissociation energies of the alkali metal hydroxides have been determined by several workers from flame studies[9-11] and by mass spectrometry.[12] The data for KOH are summarized below.

Source	Method	$\Delta_f H°(298.15\ K)$, $kcal·mol^{-1}$ 3rd law	$D°_0$(K–OH) $kcal·mol^{-1}$
Smith and Sugden[9]	Flame	86 ± 1	
Jensen and Padley[10]	Flame	36.4	82 ± 2
Cotton and Jenkins[11]	Flame	32.5	86 ± 2
Gorokhov *et al.*[12]	Mass Spec.	80 ± 3	
	Reaction: K(g) + H_2O(g) = KOH(g) + H(g)		

Our adopted enthalpy of formation for KOH(g) leads to $D°_0 = 85.4 \pm 3.0\ kcal·mol^{-1}$, which is in reasonable agreement with the results of the flame studies,[9-11] particularly when one considers the difficulties inherent in this method.

Heat Capacity and Entropy

Kuczkowski *et al.*[13] observed the microwave spectra of gaseous KOH and interpreted the results in terms of a linear geometry. Very recently, microwave studies of gaseous CsOH[14a] and RbOH,[14b] along with infrared spectra of matrix-isolated CsOH,[15a] RbOH[15b] and NaOH[15b] have been reported and interpreted in terms of linear structures for all these molecules. We adopt a linear configuration for KOH(g), along with the bond distances determined by Kuczkowski *et al.*[13] from their microwave studies.

Acquista and Abramowitz[15b] attempted to measure the infrared spectrum of matrix-isolated monomeric KOH but observed bands which could only be ascribable to polymeric species. Spinar and Margrave[16] investigated the infrared spectrum of the equilibrium gases over liquid KOH at temperatures up to 1000 K. An absorption band at 408 ± 10 cm^{-1} was assigned to the K–OH stretching by these workers, and this assignment is adopted here. The doubly degenerate bending and O–H stretching frequencies are estimates taken from the recent work of Jensen.[17]

Heat of Formation

Porter and Schoonmaker[1] obtained an appearance potential curve near threshold for KOH^+ which extrapolates to 7.8 eV at zero ion current. They presented evidence which indicated that a large fraction of KOH^+ was formed by dissociative ionization of the dimer. In a later study, these same workers[2] rejected their earlier results, since it was found that the presence of magnesia in their cell had reduced the activity of the hydroxide. Cusarov and Gorokhov[3] in a similar mass spectrometric study ofthe evaporation products of KOH have shown that KOH^+ is formed primarily from direct ionization of the hydroxide. Very recently, Gorokhov *et al.*[4] reported the appearance potential of KOH^+ from KOH as 7.5 ± 0.2 eV. We adopt this result as $\Delta_r H°$ for the process $e^- + KOH(g) \rightarrow KOH^+(g) + 2e^-$, since it is consistent with the expected mode of ionization. This value leads to $\Delta_f H°(KOH^+, g, 0\ K) = 118 \pm 10\ kcal \cdot mol^{-1}$ when used in conjunction with $\Delta_f H°(KOH, g, 0\ K) = -54.6 \pm 3.0\ kcal \cdot mol^{-1}$.[5]

Heat Capacity and Entropy

The configuration of KOH^+ is predicted to be linear by Walsh,[6] since it has seven valence electrons. The same correlation predicts that the unpaired electron is in a pi orbital, thus, the ground state of KOH^+ is $^2\Pi$. A first excited state is estimated at 32000 cm^{-1} to be $^2\Sigma$ by analogy with the isoelectronic molecules OH.[5] and SH[5] The vibrational frequencies are estimated from those for KOH with somewhat lower values to account for the effect of weaker bonding predicted for the positive ion. Similarly, the K–O and O–H bond distances are increased slightly over those for KOH.

Enthalpy of Formation

The enthalpies of solution of Li(cr) and LiH(cr) in water have been measured by Guntz[1] and Moers[2] using an open Dewar flask calorimeter and by Messer[3] and Gunn[4] using closed bomb calorimetry. Based on the reported values of the enthalpy changes ($\Delta_r H°$) for the reaction (A) Li(cr) + H_2O(l) = LiOH(aq) + 1/2 H_2(g), and (B) LiH(cr) + H_2O(l) = LiOH(aq) + H_2(g), the corresponding $\Delta_f H°$(298.15 K) for LiH(cr) are calculated. The results are presented in the table below.

The decomposition pressures of LiH(cr) have been determined by Hurd[5] at temperatures 782–926 K. By use of the 2nd and 3rd law methods, the enthalpy changes for the decomposition reaction (C) LiH(cr) = Li(l) + 1/2 H_2(g) are evaluated as 21.87 ± 0.3 and 22.34 kcal·mol^{-1}, respectively. Based on the 3rd law $\Delta_r H°$(298.15 K) and $\Delta_f H°$(Li, l, 298.15 K) = 0.569 kcal·mol^{-1}, we derive the value $\Delta_f H°$(LiH, cr, 298.15 K) = −21.77 ± 0.2 kcal·mol^{-1}, which is in good agreement with the values obtained by calorimetric method. Gunts[1] measured the decomposition pressure at 953 K for the same reaction. The 3rd law $\Delta_r H°$(298.15 K) and $\Delta_f H°$(LiH, cr, 298.15 K) are evaluated as 21.86 and 21.29 kcal·mol^{-1}, respectively.

Johnson[6] has determined the standard Gibbs energy of formation for LiH(cr) from emf measurements over the temperature range 675–885 K. The cell utilized an Armco iron flag over which H_2 was passed as the cathode and a molten Li anode. LiCl, LiBr and LiI, each saturated with LiH were used as electrolytes. Using the reported emf values at different temperatures (47 data points) for reaction (C) we derive $\Delta_f H°$(298.15 K) = 21.81 kcal·mol^{-1} for LiH(cr).

The $\Delta_f H°$(LiH, cr, 298.15 K) value reported by Gunn[4] is adopted.

Heat Capacity and Entropy

The low temperature heat capacities are obtained from the data of Kostyukov[7] 3.72–295.5 K. The $C_p°$ data reported by Gunther[8] are consistently lower than the adopted ones in the temperature range 74.0–90.5 K but considerably higher at 292.7 K. The high temperature enthalpies have been determined by Fieldhouse[9] 413.2–914.3 K and Vogt[14] 878.15–953.15 K. The derived high temperature heat capacities are joined smoothly with the low temperature values and extrapolated smoothly above 953.15 K.

$S°$(298.15 K) is calculated based on the adopted low temperature heat capacities, using $S°(7\ K) = 0.0002\ cal \cdot K^{-1} \cdot mol^{-1}$.

Fusion Data

The value of T_{fus} has been reported as 953,[1] 961 ± 1,[10, 12] 959.6[11] and 961.8 ± 0.3.[13] The value reported by Messer[13] is adopted. The heat of melting, $\Delta_{fus} H°$, has been determined as 5.095 ± 0.46[13] and 5.237 ± 0.040 kcal mol.[14] The first $\Delta_{fus} H°$ value was evaluated cryogenically from the lowering of melting point in the systems LiH–LiO_2O and LiH–CaH_2. The second value was derived from enthalpy data measured with copper block calorimeter. The adopted $\Delta_{fus} H°$ value is derived from the enthalpy data of Vogt[14] using the adopted heat capacities for LiH(cr) and LiH(l).

Sublimation Data

The value of $\Delta_{sub} H°$(298.15 K) is calculated as the difference between $\Delta_f H°$(298.15 K) for LiH(g) and LIH(cr).

$S°(298.15\ K)$ = [22.227] $J·K^{-1}·mol^{-1}$
T_{fus} = 961.8 ± 0.3 K
T_d = 1223 K

$\Delta_f H°(298.15\ K)$ = −[77.714] $kJ·mol^{-1}$
$\Delta_{fus}H°$ = 22.594 ± 0.42 $kJ·mol^{-1}$

Heat of Formation

$\Delta_f H°$(l, 298.15 K) is obtained from $\Delta_f H°$(cr, 298.15 K) by adding $\Delta_{fus}H°$ and the difference between $H°$(961.8;298.15) for crystal and liquid.

The decomposition pressures of LiH(l) at different temperatures have been investigated by Hill,[1] Perlow,[2] Johnson, and Gibb[4] Based on their reported equilibrium pressures, the enthalpy changes for the reaction LiH(l) = Li(l) + 1/2H_2(g) are evaluated by the second and third law methods. The results are presented in the table below. It should be noted that the measured decomposition pressures are highly sensitive to composition and change extremely rapidly between 99 and 100 percent purity. Therefore we give no weight to the equilibrium data.

Source	T/K	Data Points	$\Delta_f H°$(298.15 K), kcal·mol^{-1} 2nd law	3rd law	Drift cal·K^{-1}·mol^{-1}	$\Delta_f H°$(298.15K)** kcal·mol^{-1}
Hill (1938)	973.2	1	–	16.93	–	−16.36
Perlow (1941)	1043–1098	2	20.10	17.69	−2.2	−17.12
Johnson*	1050–1090	–	24.69	18.36	−5.9	−17.79
Gibb (1951)	1073–1173	2	5.66	15.2	+8.5	−14.63

*The vapor pressure values are calculated from an equation quoted by Gibb[3] but derived from the vapor pressures measured by W.C. Johnson, University of Chicago.

**Based on the third law $\Delta_f H°$(298.15 K).

Heat Capacity and Entropy

The enthalpies of LiH(l) in the temperature range 975.15–1075.15 K have been measured by Vogt.[5] Using the reported enthalpy values, the heat capacity of LiH(l) is derived as 14.9 cal·K^{-1}·mol^{-1}. This $C_p°$ value is adopted and extrapolated above and below the measured range.

$S°$(298.15 K) is obtained in a manner analogous to that of the enthalpy of formation.

Melting Data

Refer to crystal table for details.

Decomposition Data

T_{dcm} = 1223 K is calculated as the temperature at which LiH(l) decomposes into Li(l) and H_2(g) where the fugacity of H_2(g) equals one atmosphere.

Enthalpy of Formation

Velasco,[1] observed the absorption spectra of LiH(g) in the near ultraviolet with high dispersion and absorbing path lengths up to 16 meters. He found a new band system involving the ground state and a $^1\Pi$ excited state. Rotational and vibrational analyses of this system were carried out and the observed breaking off of the rotational structure of the bands was interpreted as due to predissociation by rotation. With this assumption very accurate dissociation limits of the $B^1\Pi$ state were obtained. From these dissociation limits the dissociation energy ($D°$) of the ground state of LiH was found to be 2.4288 ± 0.0002 eV. Based on this $D°$ value, we adopt $\Delta_f H°(2981.5\ K) = 33.61\ kcal·mol^{-1}$ for LiH(g)

Kemperer,[2] observed the infrared spectrum of LiH(g) in emission in the frequency region 1500 to 970 cm^{-1}, using a Perkin–Elmer double-pass monochromator with NaCl optics. Estimating the minimum LiH pressure as 10 mm and assuming the maximum possible Li pressure, he reported K = 0.005 (atm) at 1400 K for the reaction $2Li(g) + H_2(g) = 2LiH(g)$. We calculate the corresponding enthalpy change, $\Delta_r H°(1400\ K)$, to be $-9.63\ kcal·mol^{-1}$, employing $\Delta_r S°(1400\ K) = -17.407\ cal·K^{-1}·mol^{-1}$. Incorporating this $\Delta_r H°(1400\ K)$ value with $\Delta_f H°(1400\ K) = 35.601\ kcal·mol^{-1}$ for Li(g), we obtain $\Delta_f H°(298.15\ K) \leq 33.92\ kcal·mol^{-1}$ for LiH(g), which is in good agreement with the adopted value.

Gaydon,[3] derived the value $D°(LiH) = 2.5 \pm 0.2$ eV from earlier spectroscopic data.

Heat Capacity and Entropy

The third electronic level and quantum weight are obtained from Velasco.[1] All the other constants are taken fro Herzberg,[4] and corrected to the average isotopic species.

$S°(298.15\ K) = 42.821 \pm 0.21\ J \cdot K^{-1} \cdot mol^{-1}$

$\Delta_f H°(0\ K) = -479.14 \pm 0.4\ kJ \cdot mol^{-1}$

$\Delta_f H°(298.15\ K) = -484.93 \pm 0.4\ kJ \cdot mol^{-1}$

Enthalpy of Formation

The enthalpy of formation of crystalline LiOH is determined from calorimetric studies on the enthalpy of hydrolysis of metallic lithium and the enthalpy of solution of the hydroxide in water.

Reshetnikov[1] determined the enthalpy of solution of LiOH(cr) in (aq, 400 H_2O) as $-5.479 \pm 0.007\ kcal \cdot mol^{-1}$. Combining this result with enthalpy of dilution data for LiOH tabulated by Parker[2] we derive $\Delta_{sol}H°(LiOH, cr) = -5.632 \pm 0.020\ kcal \cdot mol^{-1}$, which is essentially the value recommended by Parker.[2] Lower values by some 600–650 $cal \cdot K^{-1} \cdot mol^{-1}$ for the enthalpy of solution of LiOH(cr) are summarized by Parker.[2] The discrepancy in these values probably arises from carbonate and water impurities in the LiOH samples. Since their presence would tend to reduce the enthalpy of solution, we adopt the higher results of Reshetnikov.[1]

Gunn and Green[3a,3b] and Messer *et al.*[4] measured the enthalpy of hydrolysis of metallic lithium. Their results for the reaction Li(cr) + (n+1) $H_2O \rightarrow LiOHn\ H_2O + 0.5\ H_2(g)$ are summarized below.

Source	Moles of H_2O	$\Delta_{hyd}H°(298.15\ K)$* $kcal \cdot mol^{-1}$	$\Delta_f H°(LiOH, aq, \infty, 298.15\ K)$** $kcal \cdot mol^{-1}$	$\Delta_f H°(298.15K)$ $kcal \cdot mol^{-1}$

Messer *et al.*[4]	70	-53.05 ± 0.20	-121.37 ± 0.20	-115.74 ± 0.20

*Dilution data from Parker[2]

*Based on $\Delta_f H°(H_2O, l, 298.15\ K) = -68.315\ kcal \cdot mol^{-1}$ [5]

Combination of the $\Delta_f H°(LiOH, aq, \infty, 298.15\ K)$ values with the enthalpy of solution of LiOH(cr) given above results in the values for $\Delta_f H°(LiOH, cr, 298.15\ K)$ given in the last column. The adopted value is from the work of Gunn and Green[3a,3b] with minor adjustments in the uncertainty interval to include possible errors in some of the auxiliary data used in the calculations.

Heat Capacity and Entropy

Heat capacities for LiOH(cr) in the temperature range 15–300 K are those of Bauer *et al.*[6] Heat capacities above 300 K are calculated from the high temperature (418–879 K) enthalpy data of Shomate and Cohen.[7] Both sets of data were smoothed by computer and joined at 298.15 K. The rapid rise in the enthalpy data of Shomate and Cohen[7] near the melting point is attributed to premelting and data in the temperature range 725–732 K were not used in the fit. Powers and Blalock[8] also measured high temperature (397–1213 K) enthalpy data for LiOH(cr) in a Bunsen ice calorimeter. Although their results are less precise than those of Shomate and Cohen[7] the two sets of measurements are in reasonable agreement.

$S°(298.15\ K)$ is determined from the smoothed $C_p°$ data of Bauer *et al.*[6] and is based on an extrapolation of $S°(16\ K) = 0.027\ cal \cdot K^{-1} \cdot mol^{-1}$.

Transition and Fusion Data

The adopted enthalpy of melting and melting point for LiOH are from the enthalpy measurements of Shomate and Cohen.[7] Powers and Blalock[8] reported $\Delta_{fus}H° = 5.029\ kcal \cdot mol^{-1}$ at 746 K from their enthalpy measurements on LiOH. Very recently, Reshetnikov and Baranskaya[9] reported a slightly higher value of 5.29 $kcal \cdot mol^{-1}$ at 747 K which was determined by a thermographic method.

Sublimation Data

$\Delta_{sub}H°(298.15\ K)$ values for the monomer and dimer are calculated from the adopted enthalpies of formation for the gaseous species and the crystal.

$S°(298.15\ K) = [47.969]\ J·K^{-1}·mol^{-1}$
$T_{fus} = 744.3\ K$

$\Delta_f H°(298.15\ K) = [-474.422]\ kJ·mol^{-1}$
$\Delta_{fus}H° = 20.878 \pm 0.21\ kJ·mol^{-1}$

Enthalpy of Formation

$\Delta_f H°$(LiOH, l, 298.15 K) is calculated from that of the crystal by adding $\Delta_{fus}H°$and the difference in enthalpy, $H°(744.3\ K)-H°(298.15\ K)$, between the crysal and liquid.

Heat Capacity and Entropy

The heat capacity of the liquid phase is obtained from the high temperature enthalpy measurements (750–875 K) of Shomate and Cohen.[1] We derive a constant $C_p°$ of 20.814 $cal·K^{-1}·mol^{-1}$ for LiOH(l) from these enthalpy data. The average percent deviation of the linear fit of the data was 0.2%. Powers and Blalock[2] also determined a constant $C_p° = 22.03\ cal·K^{-1}·mol^{-1}$ for LiOH(l) from enthalpy data (746–1200 K) determined by dromp calorimetry.

Fusion Data

Refer to the crystal table for details.

Vaporization Data

Dissociation pressures for LiOH(cr, l) have been measured by static,[4] effusion,[5-6] and transpiration[6] methods. These data are combined with the equilibrium studies of Berkowitz et al.[3] to give either $\Delta_{sub}H°(298.15\ K)$ or $\Delta_{vap}H°(298.15\ K)$. An analysis of the data is summerized below, and further discussion of these results is presented on the ideal gas table under Enthalpy of Formation.

Source	Reaction[a]	Method	T/K	Data Points	$\Delta_f H°(298.15\ K)$,kcal·mol^{-1} 2nd law	3rd law	Drift cal·K^{-1}·mol^{-1}	$\Delta_{sub}H°(298.15\ K)$ kcal·mol^{-1}	$\Delta_{vap}H°(298.15\ K)$ kcal·mol^{-1}

[a]A) $Li_2O(cr) + H_2O(g) = 2LiOH(g)$ B) $2LiOH(l) = Li_2O(cr) = H_2O(g)$ C) $2LiOH(cr) = Li_2O(cr) + H_2O(g)$
[b]One point rejected due to failure of a statistical test.

The boiling point, $T_{vap} = 1899$ K, is determined as the temperature at which the fugacity of LiOH(g) becomes 1 atm for the process LiOH(l) = LiOH(g). The difference in their enthalpies of formation at the boiling point is the enthalpy of vaporization, $\Delta_{vap}H° = 44.9$ kcal·mol^{-1}.

Enthalpy of Formation

Smith and Sugden[1] provided the first information on the stability of gaseous LiOH by studying its formation in hydrogen–air flames. Very recently, other flame photometric studies[3–5] have been reported on LiOH(g), primarily in connection with establishing its bond dissociation energy. Mass spectrometry[6–7] has also provided additional information on the stability of this species. These investigations have resulted in a wealth of equilibrium data involving this compound. 2nd and 3rd law analyses of these data are presented in tabular form below. Vapor pressure data for LiOH(cr, l) are analyzed under Vaporization Data (see LiOH(l) table); these data lead to $\Delta_f H°$(LiOH, g, 298.15 K) values of −59.0, −54.7, −54.8 and −58.1 kcal·mol^{-1}.

*Reactions: (A) LiOH(g) = Li(g) + OH(g) (B) Li(g) + H_2O(g) = LiOH(g) + H(g)

The equilibrium data of Sugden and co-workers[1,2] are likely to contain significant errors, since the dissociation constants were calculated with OH concentrations determined from measured flame temperatures and known gas compositions. It is now well established[8,9] that flame radical concentrations vary greatly with the distance from the reaction zone of the flame. The dissociation pressure data of Johnston and Ditmars and Johnston (refer to the LiOH(l) table) show excessive drifts which usually are indications of nonequilibrium measurements. However, even the remaining flame work[3–5] and vapor pressure data still show a scatter of over 3 kcal·mol^{-1} in $\Delta_f H°$(298.15 K) of LiOH(g). Cotton and Jenkins[4] investigated the other alkali metal hydroxides, and their data lead to $\Delta_f H°$(298.15 K) values for these compounds which are quite consistent with JANAF data.[10] On the other hand, the flame studies of McEwan and Phillips[5] as a function of temperature do not show significant drift; yet, the discrepancy between their $\Delta_f H°$(298.15 K) value and that of Cotton and Jenkins[4] is 1.6 kcal·mol^{-1}. We choose to adopt for $\Delta_f H°$(LiOH, g, 298.15 K) a weighted average of the results from the flame work[3–5] and the vapor pressure data. The adopted value $\Delta_f H°$(LiOH, g, 298.15 K) = −56.0 ± 1.5 kcal·mol^{-1} corresponds to a bond dissociation energy of $D_0°$(Li–OH) = 102.8 ± 1.5 kcal·mol^{-}.

Heat Capacity and Entropy

Freund *et al.*[11] measured the molecular beam electric resonance spectra of LiOH and calculated molecular constants on the basis of a linear equilibrium structure. Linear structures for the other alkali metal hydroxides have been proposed from microwave and infrared studies on these molecules. (Refer to the respective tables for details.) We adopt a linear configuration for LiOH and calculate a Li–O bond length from the rotational constant given by Freund *et al.*[11] The O–H bond length is estimated to be the same as for H_2O.

Experimental vibrational frequencies for LiOH have not been reported in the literature at the present time. Acquista and Abramowitz[12] have made matrix-isolation studies of monomeric CsOH, RbOH, and NaOH and provided assignments for the metal–oxygen stretch (ν_1) and the bending modes (ν_2) of these molecules. A Valence Force Treatment of the frequencies by these workers led to metal–oxygen (F_{11}), O–H (F_{33}), and bending (F_{22}) force constants. We extrapolate their data to LiOH with the result; F_{11} = 1.15 mdyn/Å, F_{33} assumed equal to 7.5 mdyn/Å with the interaction constant F_{13} = 0, and F_{22} = 0.060 mdyn Å. These estimated force constants are used to calculate the adopted frequencies by the Valence Force Treatment. Our adopted frequencies when used in an analysis of the equilibrium data from McEwan and Phillips[5] and Berkowitz *et al.*[7] (refer to the LiOH(l) table) lead to reasonable agreement between the 2nd and 3rd law $\Delta_f H°$(298.15 K) values.

Enthalpy of Formation

The enthalpy of formation, $\Delta_f H°(LiOH^+, g, 298.15\ K) = 186 \pm 25\ kcal \cdot mol^{-1}$, is calculated from the ionization potential for LiOH and $\Delta_f H°(LiOH, g, 298.15\ K) = -56.0 \pm 1.5\ kcal \cdot mol^{-1}$.[1] The ionization potential is estimated to be 10.5 ± 1.0 eV for LiOH by comparison with similar data[2] for the isoelectronic molecules LiF and LiCl. We note that this estimated value is in accord with the ionization potential of LiO (IP = 9.0 eV),[3] which should be less than LiOH since the electron in the monoxide is unpaired.

Heat Capacity and Entropy

The correlation diagram of Walsh[4] for HAB molecules predicts a linear configuration for $LiOH^+$ (seven valence electrons) with the unpaired electron in a pi orbital. Therefore, the electronic ground state of $LiOH^+$ should be $^2\Pi$. A first excited state ($^2\Sigma$) is estimated at 32000 cm^{-1} by analogy with the isoelectronic molecules OH^1 and SH.[1] The ionization of LiOH is assumed to lead to weaker bonding in $LiOH^+$, since the electron lost is a bonding one. The Li–O and O–H bond distances are increased slightly over those for LiOH to account for this weaker bonding. Similarly, the vibrational frequencies are estimated from those for LiOH with somewhat lower values.

Enthalpy of Formation

The enthalpy of formation is calculated using $D_0° = 2.0 \pm 0.5$ eV derived from a graphical extrapolation of the (0–3) energy levels of the $X^2\Sigma^+$ state reported by Gaydon.[1] Herzberg[2] reported $D_0° \leq 2.49$ eV assuming predissociation of the C^2 state of MgH into $Mg(^3P)$ and $H(^2S)$.

Heat Capacity and Entropy

The molecular constants and electronic levels are obtained from Herzberg[2] except for the electronic levels 35400 and 48000 obtained from Khan.[3]

Enthalpy of Formation

From observations made during a flame spectra study of the bond dissociation energy of magnesium oxide, Cotton and Jenkins[1] concluded that $D°_0$(Mg–OH) is less than 90 kcal·mol^{-1}. The analogy between gaseous monohydroxides and monohalides has been recognized.[2-5] Hildenbrand[6] has found that the ratio of $D°_0$(Mg–F)/$D°_0$(F–Mg–F) is 0.45; current JANAF values[7] give 0.448. From the latter ratio and current JANAF data,[7] $D°_0$(Mg–OH) = 84.49 kcal·mol^{-1} is derived. Adding the difference, −16.1 kcal·mol^{-1}, between $D°_0$(Mg–F) and $D°_0$(Ca–F)[7] to $D°_0$(Ca–OH) = 97.5 kcal·mol^{-1}[7] gives $D°_0$(Mg–OH) = 81.4 kcal·mol^{-1}. The average $D°_0$(Mg–OH) = 82.9 ± 5 kcal·mol^{-1} is adopted from which $\Delta_f H°$(MgOH, g, 0 K) = −38.56 ± 9 kcal·mol^{-1} is derived.

The value of $D°_0$(Mg–OH) = 56 ± 5 kcal·mol^{-1} derived by Bulewicz and Sugden[8] from flame spectra studies appears to be too low.

Heat Capacity and Entropy

The molecular configuration is assumed to be linear in accordance with the prediction of Walsh,[9] the evidence that the alkali metal monohydroxides are linear,[10-13] and the ESR spectrum study of MgOH in argon and neon matrices from which Brom and Weltner[13] concluded that MgOH is probably linear with a $^2\Sigma$ ground state. The analogy with MgF and MgCl[7] also indicates a $^2\Sigma^+$ ground state, which is assumed.

Ultraviolet emission spectra near 3800 Å were observed from MgOH and MgOD by Pesic and Gaydon[14] and by Brewer and Trajmar.[15] Brom and Weltner[13] observed absorption spectra of MgOH in an argon matrix in the 3100–3700 Å range. From these observations and from the comparison with MgF and MgCl, the first excited state at 27000 cm^{-1} is estimated.

The Mg–O bond distance is estimated to be slightly larger, 0.02 Å, than the MgF bond distances[7] after noting the close similarity in bond distance of the alkali metal fluorides and hydroxides. The O–H bond distance is that in water.[7]

The Mg–O stretching frequency, 718 cm^{-1}, is estimated to be the same as in MgF.[5,7] The O–H stretching frequency, 3650 cm^{-1}, is estimated from the alkali hydroxide series. The bending frequency, 492 cm^{-1}, is estimated by assuming that the ratio of the bending force constant to the stretching force constant is 0.022, which is the average ratio found in the alkali metal monohydroxides by Acquista and Abramowitz.[5,12]

The entropy in the present table is lower by 0.20 cal·K^{-1}·mol^{-1} at 298 K and 0.25 cal·K^{-1}·mol^{-1} at 1000 K than that proposed by Jackson;[5] the data relevant to the calculation are nearly the same.

Rotational Constant: B_0 = [0.491933] cm^{-1}

Enthalpy of Formation

The enthalpy of formation of $MgOH^+(g)$ is estimated based on trends suggested by the alkaline earth monohydroxide unipositive ions. The estimate is based on the close agreement of the appearance potentials of the alkaline earth monohydroxides and the corresponding monofluoride.[1] In addition, the ionization potentials of the alkaline earth elements are fairly close to the appearance potential of the monohydroxide. We adopt, as the ionization potential for MgOH(g), a value of 7.7 eV (177.57 $kcal \cdot mol^{-1}$). This value is identical to the appearance potential of MgF(g).[1] The ionization potential of Mg(g) is 7.65 eV,[1] which is very close to our adopted value.

The adopted ionization potential of 7.7 eV refers to the process $MgOH(g) + e^- = MgOH^+(g) + 2\ e^-$. Using auxiliary data,[1] we calculate $\Delta_f H°(0\ K) = 139.01 \pm 15\ kcal \cdot mol^{-1}$ for $MgOH^+(g)$. This leads to $\Delta_f H°(298.15\ K) = 139.68 \pm 15.0\ kcal \cdot mol^{-1}$.

Heat Capacity and Entropy

The molecular configuration is assumed to be linear, since experimental evidence indicates that the gaseous alkali metal hydroxides are linear.[1-4] In addition, Walsh[5] had predicted that BAH molecules (H = hydrogen atom) with ten or less valence electrons ($MgOH^+$ has 8 valence electrons) will be linear in their ground state. The molecule $MgOH^+$ is isoelectronic with NaOH.

The bond dissociation energy for $MgOH^+$ (81.7 $kcal \cdot mol^{-1}$)[1] for the process $MgOH^+(g) = Mg^+(g) + OH(g)$ is essentially identical to that for MgOH (82.0 $kcal \cdot mol^{-1}$)[1]. This suggests a similar bonding in these two molecules. Thus, the bond distances are assumed to be the same as those adopted for MgOH(g).[1] The vibrational frequencies are assumed to be similar to those adopted for MgOH(g).[1] The ground state quantum weight is assumed to be the same as that of NaOH(g).[1]

Enthalpy of Formation

The electron impact appearance potential of N_2^+ from HN_3 determined by Franklin *et al.*,[1] leads to a value $\Delta_f H°$(NH, g, 298.15 K) = 81.7 ± 0.5 kcal·mol^{-1}. Reed and Snedden[2] determined the electron impact appearance potential of NH^+ from NH_3. This, combined with the directly measured electron impact ionization potential of NH, 13.1 eV, gives $\Delta_f H°$ = 82.9 kcal·mol^{-1}. This value of the ionization potential of NH has also been obtained by Foner and Hudson.[3] However, all of these electron impact experiments are subject to errors of several tenths of an electron volt or more.

More recently, Seal and Gaydon[4] measured the concentration of NH in reflected shock waves in nitrogen–hydrogen–krypton and ammonia–krypton mixtures. These led to $D_0°$(NH) = 3.21 ± 0.16 eV, corresponding to $\Delta_f H°$(NH, g) = 90.13 ± 3 kcal·mol^{-1}. Kaskan and Nadler[5] determined NH, NH_3, and OH concentrations in a flat NH_3–D_2–N_2 flame and concluded $\Delta_f H°$(NH, g) = 90 ± 4 kcal·mol^{-1}. Stedman[6] studied the NH emission spectrum obtained by collision of metastable rare gas atoms with HN_3. Taking the highest level of NH as observed in emission as a limit, he concluded that $\Delta_f H°$(NH, g) > 80 kcal·mol^{-1}. From analogous consideration on N_2 emission observed by collision of metastable argon atoms with HN_3 he concluded that $\Delta_f H°$(NH, g) ≤ 94 kcal·mol^{-1}.

Quantum chemical calculation of the dissociation energy of small molecules is possible with estimated accuracies of 0.1 to 0.2 eV. A theoretical calculation of the dissociation energy of NH($X^3\Sigma^-$), applying the techniques of Wahl and Das[7] has been determined by Stevens[8] to yield D_e = 3.4 eV. This result corroborates the results of Seal and Gaydon and would support $\Delta_f H°$(NH, g) = 90 ± 4 kcal·mol^{-1}. Theoretical calculations of this type can be used to distinquish between disparate experimental results that differ by more than 0.2 eV.

Heat Capacity and Entropy

The vibrational and rotational constants for the ground and excited states are taken from the sources indicated. The splitting between the $X^3\Sigma^-$ and $a^1\Delta$ states is based on the work of Gilles *et al.*[14] who observed the $b^1\Sigma^+$–$X^3\Sigma^-$ band in emission.

The thermodynamic functions are calculated using first-order anharmonic corrections to Q_r^i and Q_v^i in the partition function $Q = Q_{ti}\Sigma Q_r{}^i Q_v{}^i g_i \exp(-c_2\epsilon_i/T)$. The National Bureau of Standards prepared this table[9] by critical analysis of data existing in 1972 using only the ground electronic state. Using the molecular constants selected here and $\Delta_f H°$ selected by NBS,[9] we recalculate the table in terms of 1973 fundamental constants,[10] 1975 atomic weights[11] and current JANAF reference states for the elements.

Product of the Moments of Inertia: $I_A I_B I_C = 5.939 \times 10^{-118}\ g^3·cm^6$

Enthalpy of Formation

$\Delta_f H°$(HNO, g, 298.15 K) is calculated from $D°_0$(H–NO) = 48.6 kcal·mol^{-1} reported by Clement and Ramsay.[1]

Heat Capacity and Entropy

Vibrational frequencies were assigned by Bancroft *et al.*[2] and Brown and Pimentel[3]. Bond distances and bond angles were taken from Bancroft *et al.*[2] The molecular constants given by Dalby[4] were: r(N=O) = 1.211$_6$ Å; r(N–H) = 1.0628 Å, and a H– N=O bond angle of 108.5$_8$°. The principal moments of inertia are: $I_A = 0.1262 \times 10^{-39}$, $I_B = 2.1070 \times 10^{-39}$, and $I_C = 2.2332 \times 10^{-39}$ g·cm^2.

Ground State Quantum Weight: [1] $\sigma = 1$
Point Group: C_s
Bond Distances: O–N = 1.20 Å N–O' = 1.46 Å O–H = 0.98 Å
Bond Angles: O–N–O' = 114° N–O'–H = 103°
Product of the Moments of Inertia: $I_A I_B I_C = 5.51348 \times 10^{-116}\ g^3·cm^6$

Enthalpy of Formation

Ashmore and Tyler[1] reported $\Delta_f H°(298.15\ K) = -9.06 \pm 0.32\ kcal·mol^{-1}$ for the reaction: $NO(g) + NO_2(g) + H_2O(g) = 2\ HNO_2(g)$, yielding $\Delta_f H°(298.15\ K) = -18.57 \pm 0.20\ kcal·mol^{-1}$ for HNO_2(g). Jones *et al.*[2] estimated the difference in energy of cis– and trans– HNO_2(g) to be $506 \pm 250\ cal·K^{-1}·mol^{-1}$. Hence the value of $\Delta_f H°(298.15\ K)$ for cis–HNO_2(g) was calculated.

The heat of reaction and the equilibrium constants for the formation of HNO_2(g) have been calculated by Karavaev and Skvortsov.[3] The value of $\Delta_f H°(298.15\ K)$ reported is $-18.8\ kcal·mol^{-1}$. However, based on the enthalpy of formation of liquid HNO_2, Ashmore and Levitt[4] give $\Delta_f H° = -13.7\ kcal·mol^{-1}$. The corresponding value reported by Rosser and Wise[5] is $-20.0\ kcal·mol^{-1}$, based on the experimental data of Wayne and Yost,[6] and the entropy of the equilibrium mixture of the trans– and cis– HNO_2(g) calculated by Jones, *et al.*[2]

Heat Capacity and Entropy

Vibrational frequencies, bond distances, and bond angles were obtained from Dor and Tarte[7] and Jones *et al.*[2] The principal moments of inertia are: $I_A = 1.0282 \times 10^{-39}$, $I_B = 6.8267 \times 10^{-39}$, and $I_C = 7.8549 \times 10^{-39}\ g·cm^2$.

Ground State Quantum Weight: [1] $\sigma = 1$

Point Group: C_s

Bond Distances: O–N = 1.20 Å N–O' = 1.46 Å O'–H = 0.98 Å

Bond Angles: O–N–O' = 118° N–O'–H = 105°

Product of the Moments of Inertia: $I_A I_B I_C = 4.91660 \times 10^{-116}\ g^3·cm^6$

Enthalpy of Formation

Ashmore and Tyler[1] reported $\Delta_f H°(298.15\ K) = -9.06 \pm 0.32\ kcal·mol^{-1}$ for the reaction: $NO(g) + NO_2(g) + H_2O(g) \rightarrow 2HNO_2$ (g), yielding $\Delta_f H°(298.15\ K) = -18.57 \pm 0.20\ kcal·mol^{-1}$ for HNO_2(g). Jones *et al.*[2] estimated the difference in energy of cis– and trans–HNO_2(g) to be $506 \pm 250\ cal·K^{-1}·mol^{-1}$. Hence the value of $\Delta_f H°(298.15\ K)$ for trans–HNO_2(g) was calculated.

The heat of reaction and the equilibrium constants for the formation of HNO_2(g) have been calculated by Karavaev and Skvortsov.[3] The value of $\Delta_f H°(298.15\ K)$ reported is $-18.8\ kcal·mol^{-1}$. However, based on the enthalpy of formation of liquid HNO_2, Ashmore and Levitt[4] give $\Delta_f H° = -13.7\ kcal·mol^{-1}$. The corresponding value reported by Rosser and Wise[5] is $-20.0\ kcal·mol^{-1}$, based on the experimental data of Wayne and Yost[6] and the entropy of the equilibrium mixture of the trans– and cis– HNO_2(g) calculated by Jones *et al.*[2]

Heat Capacity and Entropy

Vibrational frequencies, bond distances, and bond angles were taken from Jones *et al.*[2] The values of vibrational frequencies were in good agreement to those reported by Dor and Tarte.[7] The principal moments of inertia are: $I_A = 0.7855 \times 10^{-39}$, $I_B = 7.5286 \times 10^{-39}$, and $I_C = 8.3141 \times 10^{-39}\ g·cm^2$.

Bond Angles: O–N–O = 130° ± 20' N–O' H = 102° ± 30'
Product of the Moments of Inertia: $I_A I_B I_C = 5.988123 \times 10^{-115}\ g^3·cm^6$

Enthalpy of Formation

$\Delta_f H°(298.15\ K)$ was taken from.[1] Equilibria involving HNO_3 were measured by Jones,[2] Feick,[3] and Abel, *et al.*,[4] yielding $\Delta_f H° = -32.06$, -32.02, and $-32.09\ kcal·mol^{-}$, respectively. Becker and Roth[5] and Thomsen[6] measured the enthalpy of neutralization of HNO_3(aq) with NH_3, combining these values with the data for NH_4NO_3 yields $\Delta_f H° = -32.27$ and $-32.07\ kcal·mol^{-1}$. Berthelot[7] measured the enthalpy of reaction of N_2O_4(g) and Cl_2(g), obtaining $\Delta_f H° = -32.10\ kcal·mol^{-1}$. The value of $\Delta_f H°(298.15\ K)$ reported by Forsythe and Giauque[8] was $-31.994\ kcal·mol^{-1}$. The value adopted is the weighted average of these six values.

Heat Capacity and Entropy

Vibrational frequencies were obtained from Palm and Kilpatrick.[9] Bond distances and bond angles were taken from Millen and Morton.[10] The basic parameters of HNO_3(g) reported by Akishin *et al.*[1] were: r(N=O) = 1.22 ± 0.01 ; r(N–O) = 1.40 ± 0.01 A; and the bond angle (O–N–O) = 135° ± 2.5°. Forsythe and Giauque[8] have calculated the absolute entropy of pure nitric acid (g) from calorimetric data. The value obtained was $S°(298.15\ K) = 63.62\ cal·K^{-1}·mol^{-1}$. The entropy of nitric acid vapor at 298.15 K has also been computed by Cohn *et al.*[9] to be $63.70\ cal·K^{-1}·mol^{-1}$. The prinicpal moments of inertia are: $I_A = 6.3868 \times 10^{-39}$, $I_B = 7.0025 \times 10^{-39}$, and $I_C = 13.3893 \times 10^{-39}\ g·cm^2$.

PREVIOUS: June 1963 (1 atm) CURRENT: June 1963 (1 bar)

$S°(298.15\ K) = 40.016\ J·K^{-1}·mol^{-1}$

$\Delta_f H°(0\ K) = -52.021 \pm 0.08\ kJ·mol^{-1}$
$\Delta_f H°(298.15\ K) = -56.442 \pm 0.08\ kJ·mol^{-1}$

Enthalpy of Formation

$\Delta_f H°(298.15\ K)$ was obtained from Gunn and Green.[1] The value of $\Delta_f H°(298.15\ K)$ reported by Messer *et al.*[2] was $13.60 \pm 0.27\ kcal·mol^{-1}$ which is in excellent agreement with the value given by Gunn and Green.[1] The results of the previous investigations were also reviewed by Messer, *et al.*[2]

Heat Capacity and Entropy

$C_p°$ below 350 K were measured by Westrum, *et al.*[3] $C_p°$ above 350 K were estimated by comparison with those for LiH(cr). $C_p°$ (59.94–91.84 K) were also measured by Sayre and Beaver.[4] $S°(T)$ at 100, 200, and 298.15 K were taken from Westrum *et al.*[3] using the extrapolated value $S°(10\ K) = 0.008\ cal·K^{-1}·mol^{-1}$.

Decomposition Data

T_{dcm} was estimated from the value of $\Delta_f G°$ in the table. The table of T_{dcm} given by Banus *et al.*[5] was 940 K. It was assumed that NaH would behave similarly to LiH and that decomposition pressures would be purity dependent, and this would produce apparently high decomposition temperatures.

$B_e = 4.9012\ cm^{-1}$ $\alpha_e = 0.1353\ cm^{-1}$

Enthalpy of Formation

$\Delta_f H°(298.15\ K)$ is calculated from $D_0^0 = 2.05 \pm 0.2$ eV reported by Gaydon.[1]

Heat Capacity and Entropy

All molecular and spectroscopic constants were obtained from Herzberg.[2]

$S°(298.15\ K) = 64.445 \pm 0.84\ J \cdot K^{-1} \cdot mol^{-1}$
$T_{trs} = 572\ K$
$T_{fus} = 596\ K$

$\Delta_f H°(0\ K) = -421.40 \pm 0.4\ kJ \cdot mol^{-1}$
$\Delta_f H°(298.15\ K) = -425.93 \pm 0.4\ kJ \cdot mol^{-1}$
$\Delta_{trs} H° = 7.196 \pm 0.84\ kJ \cdot mol^{-1}$
$\Delta_{fus} H° = 6.611 \pm 0.84\ kJ \cdot mol^{-1}$

Enthalpy of Formation

The enthalpy of formation of NaOH(cr) is obtained from its enthalpy of solution in water, the enthalpy of hydrolysis of metallic sodium, and appropriate auxiliary data.

Reshetnikov[1] determined calorimetrically the enthalpy of solution of NaOH in aq, 400 H_2O as -10.445 ± 0.015 kcal·mol^{-1}. Combining this result with enthalpy of dilution data for aqueous sodium hydroxide solutions tabulated by Parker[2] we derive $\Delta_{sln}H°$(NaOH, cr) = -10.56 ± 0.02 kcal·mol^{-1}. Murch and Giauque[3] measured the heats of solution in water of a series of solids which contained various amounts of water in the range NaOH·(0.1 to 1) H_2O. Their data indicated a linear relationship between the heat of solution and the ratio of the moles of water to the moles of sodium hydroxide. Upon extrapolation their data gave $\Delta_{sln}H°$(NaOH, cr) = -10.637 ± 0.010 kcal·mol^{-1}.[2] This latter value is adopted here, since the extrapolation to zero moles of water tends to eliminate its effect on the heat of solution.

The enthalpy of hydrolysis of metallic sodium has been determined by various investigators.[4–6] For the reaction Na(cr) + (n+1)H_2O → NaOH·n H_2O + 0.5 H_2(g) data are summarized below.

Source	n moles of H_2O	$\Delta_h H°$(298.15 K) kcal·mol^{-1}	$\Delta_f H°$(NaOH·aq, ∞)* kcal·mol^{-1}	$\Delta_f H°$(NaOH, cr, 298.15 K) kcal·mol^{-1}
Gunn and Green[4a,4b]	∞	−44.124 ± 0.015	−112.439	−101.80
Messer *et al.*[5]	∞	−44.22 ± 0.20	−112.53	−101.88
Ketchen and Wallace[6]	∞	−44.05 ± 0.20	−112.37	−101.72

*Based on $\Delta_f H°(H_2O, l, 298.15\ K) = 68.315$ kcal·mol^{-1}.[7]

Combination of the $\Delta_f H°$(NaOH·aq,∞, 298.15 K) values with the enthalpy of solution of NaOH(cr) at infinite dilution given above, results in the $\Delta_f H°$(NaOH, cr, 298.15 K) values given in the last column. The value determined from the work of Gunn and Green[4] is adopted.

Earlier determinations of $\Delta_f H°$(NaOH, cr, 298.15 K) have been summarized by Bichowsky and Rossini[8] and are not listed here.

Heat Capacity and Entropy

Murch and Giauque[3] determined low temperature heat capacities for NaOH·O.04014 H_2O and NaOH·0.97776 H_2O from 15 to 320 K. From these data heat capacities for anhydrous NaOH(cr) were calculated and joined smoothly at 298.15 K with the high temperature (273–973 K) enthalpy data of Douglas and Dever.[9] These smoothed heat capacities given by Murch and Giauque are adopted. Low temperature heat capacity data for NaOH(cr) in the temperature range 60 to 300 K have also been reported by Kelley and Snyder.[10] The deviations of their data from the adopted values range from a few tenths of a percent (150–300 K) to up to about 30% at the lowest temperatures investigated (60 K). Popov and Ginzburg[11] also determined high temperture enthalpy data (293–1016 K) for NaOH by drop calorimetry. Their reported value $H°(500\ K) - H°(298.15\ K) = 3.112$ kcal·mol^{-1} [11] is in very good agreement with the tabulated value of 3.176 kcal·mol^{-1}.

$S°(298.15\ K)$ is based upon the extrapolated value of 0.020 cal·K^{-1}·mol^{-1} at 15 K.

Transition and Fusion Data

The adopted enthalpies of the polymorphic transformation and fusion of NaOH are mean values from the work of Douglas and Dever[9] Popov and Ginzburg[11] and Reshetnikov and Baranskaya.[12] T_{trs} and T_{fus} are from Reshetnikov and Baranskaya.[12]

Sublimation Data

$\Delta_{sub}H°(298.15\ K)$ for the monomer and dimer are calculated from the adopted enthalpies of formation of the crystal and the respective gaseous species.

PREVIOUS: March 1966 CURRENT: December 1970

$S°(298.15\ K) = [75.891]\ J·K^{-1}·mol^{-1}$ $\Delta_f H°(298.15\ K) = [-416.878]\ kJ·mol^{-1}$

$T_{fus} = 596\ K$ $\Delta_{fus}H° = 6.611 \pm 0.84\ kJ·mol^{-1}$

Enthalpy of Formation

$\Delta_f H°$(NaOH, l, 298.15 K) is calculated from that of the crystal by adding $\Delta_{fus}H°$ and the difference in enthalpy, $H°$(596 K)–$H°$(298.15 K), between the crystal and liquid.

Heat Capacity and Entropy

The adopted heat capacities for NaOH(l) in the temperature range 596 to 1000 K are from the enthalpy measurements of Douglas and Dever.[1] The heat capacities below the melting point and above 1000 K are extrapolated from the experimental heat capacity curve. Powers and Blalock[2] reported $C_p°$(l) = 19.6 $cal·K^{-1}·mol^{-1}$ from enthalpy measurements, in a short temperature range, by drop calorimetry. The smoothed enthalpy data for NaOH(l) reported by Popov and Ginzburg[3a,3b] are from 0.2 to 0.5 $kcal·mol^{-1}$ less than the adopted values in the temperature range 700 to 1000 K.

$S°$(298.15 K) is calculated in a manner analogous to that used for the enthalpy of formation.

Fusion Data

Refer to the crystal table for details.

Vaporization Data

T_{vap} = 1830 K (for monomer) is calculated as the temperature at which the fugacity of NaOH(g) is 1 atm for the process NaOH(l) = NaOH(g). The difference in the enthalpies of formation of NaOH(l) and NaOH(g) at the T_{vap} is the enthalpy of vaporization, $\Delta_{vap}H° = 175.310\ kJ·mol^{-1}$.

Wartenberg and Albrecht[4] reported a boiling point of 1661 K from their static vapor pressure data. However, these workers observed the presence of water after each experiment which may indicate some decomposition of the sample. See the ideal gas table for further discussion.

Enthalpy of Formation

The bond dissociation energies of the alkali metal hydroxides have been the subject of a number of investigations[1–4] in recent years. The majority of this work has involved equilibrium studies on the reaction A(g) + H_2O(g) = AOH(g) + H(g), where A is an alkali metal, in hydrogen oxygen nitrogen flames containing water. In the case of NaOH, data are summarized below:

Source	Method	Reaction*	Data Points	T/K	$\Delta_r H°$(298.15 K),kcal·mol^{-1} 3rd law	$D°$(Na–OH, 0 K) kcal·mol^{-1}
Jensen and Padley[2a]	Flames	A	1	2475	40.5	77.9
Cotton and Jenkins[4]	Flames	A	1	2030	36.6	81.8

*(A) Na(g) + H_2O(g) = NaOH(g) + H(g)

We note that Cotton and Jenkins[4] in the same paper reported bond dissociation energies for LiOH(g) and KOH(g) which are in reasonable agreement with JANAF values[5] for the enthalpy of formation of these two compounds. Furthermore, bond dissociation data for the alkali metal halides[6] clearly establish the sodium compound as the least stable within each halide series. The potassium and sodium compounds differ by from 4.3 kcal·mol^{-1} for the fluorides and bromides to 3.6 kcal·mol^{-1} for the chlorides. It seems most likely that this same trend in the bond dissociation energies would apply to the hydroxides as well. Based upon these correlations, we adopt $D_0°$(Na–OH) = 81.5 ± 3.0 kcal·mol^{-1} with $D_0°$(K–OH)–$D_0°$(Na–OH) = 3.9 kcal·mol^{-1}. This value corresponds to $\Delta_f H°$(NaOH, g, 298.15 K) = −47.3 ± 3.0 kcal·mol^{-1}.

Wartenberg and Albrecht[7] determined vapor pressures for NaOH(l) in the temperature range 1283–1681 K by a static method. In order to evaluate $\Delta_{vap}H°$(NaOH, l, 298.15 K), we have used a trial and error variation of $\Delta_{vap}H°$(298.15 K) for the monomer and dimer, such that these values are in accordance with the adopted enthalpy of dimerization (refer to the $Na_2(OH)_2$(g) table), and the sum of the calculated partial pressures for NaOH(g) and $Na_2(OH)_2$(g) in good agreement with the experimental vapor pressure data. The resulting values are: $\Delta_{vap}H°$(to monomer) = 48.25 kcal·mol^{-1} and $\Delta_{vap}H°$(to dimer) = 48.8 kcal·mol^{-1}. From the enthalpy of vaporization of the monomer, we derive $\Delta_f H°$(NaOH, g, 298.15 K) = −51.4 kcal·mol^{-1}. This value corresponds to a bond dissociation energy for NaOH(g) that is slightly greater than the adopted value for KOH(g),[5] and thus not in line with the established trends in $D_0°$ discussed above. Buchler and Berkowitz Mattuck[8] in their review on gaseous ternary compounds of the alkali metals point to the decomposition of NaOH in the condensed phase with a resulting change in composition as the major problem in the interpretation of thermodynamic measurements on this system. Until the nature of the condensed phase and the relationship between the vapor and condensed phase composition for NaOH(l) are established, an accurate enthalpy of vaporization will remain undetermined.

Heat Capacity and Entropy

The infrared spectra of matrix isolated NaOH and NaOD have been recently observed by Acquista and Abramowitz.[9] The alkali–metal–oxygen stretching frequency, ν_1, and the bending mode, ν_2, for NaOH were assigned as 431 and 337 cm^{-1}, respectively, by these workers. The isotope shift of ν_2 was consistent with a linear structure for NaOH having bond lengths of 1.93 and 0.97 Å for the Na–O and O–H bonds. We have adopted a linear configuration for NaOH with the bond lengths and frequencies given above. Spinar and Margrave[10] assigned ν_1 as 437 ± 10 cm^{-1} for NaOH which is in good agreement with the adopted value. The O–H stretching frequency, ν_3, was estimated by Jensen.[2b]

Enthalpy of Formation

Beckett and Cassidy[1] selected the ionization potential of NaOH as 9.0 ± 1.0 eV (207.6 ± 23 kcal·mol^{-1}). A measured value of roughly 9 eV has been reported by Schoonmaker and Porter.[2] Combining this result with JANAF auxiliary data,[3] we derive $\Delta_f H°(NaOH^+, g, 0\ K) = 161 \pm 25$ kcal·mol^{-1}, which is tentatively adopted.

Heat Capacity and Entropy

$NaOH^+$ has seven valence electrons. According to the correlation diagram of Walsh[4] for HAB type molecules, NaOH+ should be linear with the unpaired electron in a pi orbital. Therefore, we assume the ground state to be $^2\Sigma$. A first excited state is estimated at 32000 cm^{-1} to be $^2\Sigma$ by analogy with the isoelectronic molecules OH[3] and SH.[3] The removal of a bonding electron from NaOH to form $NaOH^+$ should lead to weaker bonding in the positive ion. Consequently, the vibrational frequencies are estimated to be somewhat lower than those for NaOH. Similarly, the Na–O and O–H bond distances are increased slightly over those for NaOH.

Enthalpy of Formation

$\Delta_f H°$(OH, g, 0 K) is calculated from the relation $\Delta\ H°(OH, g, 0\ K) = 1/2\ D_0°(O_2) + 1/2\ D_0°(H_2) = D_0°(OH)$. are as follows: $D_0°(O_2) = 117.967 \pm 0.042\ kcal\cdot mol^{-1}$ and $D_0°(H_2) = 103.267 \pm 0.003\ kcal\cdot mol^{-1}$ were taken from the CODATA[1] selection. Barrow[2] in a refinement of the work of Barrow and Downie[3] obtains a value of $D_0°$ for $OH(X^2\Pi_{3/2}) \rightarrow O(^3P_2) + H(^2S_{1/2})$ of 35427 cm^{-1} from an extrapolation of $\Delta_{vap}G$ versus v; it was increased to $35450 \pm 100\ cm^{-1}$ to account for the fact that $\Delta_{vap}G$ yields slightly low values at high v. Fehlenbok[4] obtains a value of D_e for $OH(B^2\Sigma^+)$ of 1315 cm^{-1} and G(O) for this state of 441 cm^{-1}. Using $T_e(B^2\Sigma^+)$ given by Rosen[5] and the zero point energy of HO (including the Dunham correction, see Herzberg[6] of 847.0 cm^{-1}, this yields $D_0°(OH) = 35451\ cm^{-1}$ with an estimated uncertainty of 100 cm^{-1}. A value of $D_0°(OH) = 35450 \pm 100\ cm^{-1} = 101.356 \pm 0.29\ kcal\cdot mol^{-1}$ was adopted. Combining the above values, one obtains $\Delta_f H°(OH, g, 0\ K) = 9.261 \pm 0.29\ kcal\cdot mol^{-1}$ which is in good agreement with the last JANAF[7] selection.

A review of earlier work is given in references.[7-9]

Heat Capacity and Entropy

The vibrational and rotational constants of the respective electronic levels were taken from Rosen.[5] Comparison of the results of these calculations with those of the more exact treatment given by Haar *et al.*[10] suggests that errors in the tables due to approximations in our calculations may be neglected above 400 K. Below this, they may be appreciable. It is recommended that $H°(0\ K)$–$H°(298.15\ K)$, $S°(298.15\ K)$ and $C_p°(298.15\ K)$ be taken as $-2.107\ kcal\cdot mol^{-1}$, $43.890\ kJ\cdot mol^{-1}$, and $7.144\ kJ\cdot mol^{-1}$, respectively. These errors result from dealing with the ground state ($X^2\Pi_i$) as two separate electronic states separated by 139.7 cm^{-1}

The thermodynamic functions are calculated using first–order anharmonic corrections to Q_r^i and Q_v^i in the partition function $Q = Q_t \Sigma Q_r^i Q_v^i g_i \exp(-c_2\epsilon_i/T)$. The National Bureau of Standards prepared this table[11] by critical analysis of data existing in 1972. Using molecular constants and $\Delta_f H°$ selected by NBS,[11] we recalculate the table in terms of 1973 fundamental constants,[12] 1975 atomic weights[13] and current JANAF reference states for the elements.

Enthalpy of Formation

The ionization potential of hydroxyl has been determined by Mann *et al.*[1] as 13.6 eV and by Foner and Hudson[2] as 13.18 ± 0.1 eV, both by electron impact methods. These values correspond to $\Delta_f H°(OH^+, g, 0\ K) = 322.97\ kcal \cdot mol^{-1}$ and 313.28 ± 2.5 $kcal \cdot mol^{-1}$, respectively. Metzger and Cook[3] have reported the photoionization onset of the process $H_2O(g) + h\nu \rightarrow OH^+ + H + e^-$ as 18.3 eV, with JANAF auxiliary data[4] this gives $\Delta_f H°(OH^+, g, 0\ K) = 313.3\ kcal \cdot mol^{-1}$, which is adopted.

Heat Capacity and Entropy

The measured electronic levels are those reported by Merer *et al.*,[5] the rotational constants are derived from this analysis also. The estimated electronic level is from the Hartree–Fock calculations of Cade.[6]

The vibrational constants are estimated so that $\Delta G_{1/2}$ is equal to that reported by Merer *et al.*[5] The anharmonicity, $\omega_e x_e$, is estimated by comparison with OH and NH. Calculations of $\omega_e x_e$ based on the Morse potential curve and the relation $\omega_{e2} = 4B_e^3/D_e$, or $\omega_{o2} = 4\omega_o x_o D_0^{07}$ do not appear to yield values which are preferable to our estimates; this is due to the inexactness of the potential for ionic molecules.

Enthalpy of Formation

Branscomb[1] has obtained an electron affinity of OH of 1.83 ± 0.04 eV (42.2 ± 0.9 kcal·mol^{-1}) from the photodetachment spectrum of OH^-. The vibrational state was identified as the ground state since no other absorption sequence could be detected by a thorough search. Kay and Page[2] have also determined the electron affinity by the magnetron method and report 49.1 at 1820 K, which reduces to 40 ± 2.7 kcal·mol^{-1} at 0 K. They also disclaim prior papers, Page[3] and Page and Sugden,[4] which supported higher values. Feugier and Queraud[5] have reported an electron affinity at 2250 K of 2.13 eV (49.1 kcal·mol^{-1}) which reduces to 37.7 kcal·mol^{-1} at 0 K. We adopt the value reported by Branscomb[1] which yields $\Delta_f H°(OH^-, g)$ 0 K = −32.85 kcal·mol^{-1}.

Heat Capacity and Entropy

Branscomb[1] deduced from his photodetachment spectra that ω_e, B_e and r_e are very close to the values for OH(g). Our adopted values are from the calculations of Cade[6] corrected for the mean deviations in OH and HF. The values of $\omega_e x_e$ and α_e were estimated by comparison with OH(g) and other related hydrides. The ground state configuration was assumed to be that of HF(g) with which OH^- is isoelectronic.

Enthalpy of Formation

The adopted enthalpy of formation is based on assessment of $D_0°$ values derived from flame spectra of CaOH, SrOH, and BaOH. Cotton and Jenkins[1] found both the alkaline earth monohydroxides and dihydroxides to be present in significant amounts in fuel– rich hydrogen–oxygen–nitrogen flames. They determined equilibrium constants for the reactions $M(g) + H_2O(g) = MOH(g) + H(g)$ and $M(g) + 2\ H_2O(g) = M(OH)_2(g) + 2\ H(g)$ and derived $D_0°$ values. For $D_0°$(Sr–OH), Cotton and Jenkins[1] gave 103 ± 5 kcal·mol^{-1}. Ryabova and Gurvich[2] considered SrOH to be the dominant compound and reported $D_0° = 95 \pm 8$ kcal·mol^{-1}. Sugden and Schofield[3] interpreted $Sr(OH)_2$ as dominant. Cotton and Jenkins[1] have recalculated the work of Ryabova and Gurvich[2] and of Sugden and Schofield[3] considering both SrOH and $Sr(OH)_2$ to be present and have obtained the recalculated $D_0°$(Sr–OH) values of 96 and 101 kcal·mol^{-1}, respectively. Gurvich *et al.*[4] made further measurements, interpreted SrOH as dominant, and reported $D_0°(Sr–OH) = 93 \pm 3$ kcal·mol^{-1}. Kalff and Alkemade[5] chose flame conditions to minimize the dihydroxide formation and determined a 3rd law analysis of the experimental equilibrium constants tabulated by Cotton and Jenkins[1] using current JANAF auxiliary data[7] leads to $D_0°$(Sr–OH) = 103.7 kcal·mol^{-1} which is 0.7 kcal·mol^{-1} higher than the 103 kcal·mol^{-1} given by Cotton and Jenkins.[1] Applying the correction to the value of Ryabova and Gurvich[2] and Sugden and Schofield[3] as recalculated by Cotton and Jenkins[1] gives $D_0°$(Sr–OH) = 96.7 and 101.7 kcal·mol^{-1}, respectively.

Because the corrected dissociation energy of Ryabova and Gurvich was near the adopted value for $Ba(OH)_2(g)$,[7] their corrected value was adopted for $Sr(OH)_2(g)$.[7] While their corrected value for BaOH(g)[7] is not as close to the adopted value as in the dihydroxide case, it is nevertheless the nearest one, and therefore $D_0°$(Sr–OH) = 96.7 kcal·mol^{-1} is adopted.

The ratio of the dissociation energies of the alkaline earth monohalides to those of the corresponding dihalides range from 0.40 to 0.51 with the ratio for the strontium fluorides being 0.49.[7] The similarity between the halides and hydroxides has been established.[8–11] The ratio of the adopted values for the dissociation energies of SrOH(g) and $Sr(OH)_2$ is 0.49 where $D_0°$ of the dihydroxide is defined by the reaction $Sr(OH)_2(g) = Sr(g) + 2\ OH(g)$ and is 198.6 kcal·mol^{-1}.[7]

$\Delta_f H°$(SrOH, g, 0 K) = −48.11 ± 5 kcal·mol^{-1} is calculated from the adopted dissociation energy.

Heat Capacity and Entropy

The analogy between gaseous monohydroxides and monohalides, particularly the monofluorides, has been recognized.[8–11] The molecular configuration is assumed to be linear in accordance with the prediction of Walsh[12] and the evidence that the gaseous alkali metal hydroxide are linear.[13–15] The ground state is assumed to be $^2\Sigma^+$ by analogy with SrF and SrCl.[7] The electronic levels are estimated from the band spectra observed by James and Sugden,[16] Lagerqvist and Huldt,[17] Charton and Gaydon,[18] Zhitkevich *et al.*,[19] and Van der Hurk *et al.*,[20] and the comparison with SrF and SrCl.[7]

The Sr–O bond distance is estimated to be slightly larger, 0.02 Å, than the Sr–F distance[7] after noting the close similarity in the bond distance of the alkali metal fluorides and hydroxides. The O–H bond distance is that in water.[7]

The Sr–O stretching frequency, 498 cm^{-1}, is estimated to be the same as the Sr–F stretching frequency.[7, 11] The O–H stretching frequency, 3650 cm^{-1}, is estimated from the alkali hydroxide series. The bending frequency, 438 cm^{-1}, is estimated by assuming that the ratio of the bending force constant to the stretching force constant is 0.022, which is the average ratio found in the alkali metal monohydroxides by Acquista and Abramowitz.[11, 15]

The entropy in the present table is lower by 0.06 cal·K^{-1}·mol^{-1} at 298.15 K and 0.10 cal·K^{-1}·mol^{-1} at 1000 K than that proposed by Jackson;[11] the data relevant to the calculation are nearly the same.

Enthalpy of Formation

The ionization potential of SrOH(g) was deduced by Kelly an Padley[1] to be 5.55 ± 0.1 eV. Using a rotating single probe, these authors quantitatively examined the total positive ion concentrations produced from Sr aqueous salt solutions in fuel rich, premixed $H_2 + O_2 + N_2$ flames. Using current JANAF auxiliary data,[2] we recalculate the ionization potential to be 5.75 eV.

Jensen[3] determined $\Delta_f H°(0\ K) = 25 \pm 8\ kcal·mol^{-1}$ for $Sr(g) + OH(g) = SrOH^+(g) + e^-$ in atmospheric pressure $H_2 + O_2 + N_2$ flames using the microwave cavity resonance method. This value was calculated assuming a bent molecule for $SrOH^+$; the value is not significantly changed, within the uncertainty, by the change in the configuration. Using auxiliary data[2], we derive an ionization potential of 5.28 eV, which is in fair agreement with the value derived from the data of Kelly and Padly.[1]

We adopt IP = 5.39 eV (124.30 $kcal·mol^{-1}$) which is an average of the above two studies.[1,3] This leads to $\Delta_f H°(0\ K) = 76.19\ kcal·mol^{-1}$ and $\Delta_f H°(298.15\ K) = 76.67\ kcal·mol^{-1}$ for $SrOH^+(g)$. We assign an uncertainty of $\pm 15\ kcal·mol^{-1}$.

In comparison, the ionization potential of SrF(g) is 5.03 eV[2] while that of Sr(g) is 5.692 eV.[4] Note that the average of these two values is very close to our adopted ionization potential.

Heat Capacity and Entropy

The molecular configuration is assumed to be linear, since experimental evidence indicates that the gaseous alkali metal hydroxides are linear.[2,5–7] In addition, Walsh[8] had predicted that BAH molecules (H = hydrogen atom) with ten or less valence electrons ($SrOH+$ has eight valence electrons) will be linear in their ground state. The molecule $SrOH^+$ is isoelectronic with RbOH.

The bond dissociation energy for $SrOH^+$ (103.7 $kcal·mol^{-1}$),[2, 4] for the process $SrOH^+(g) = Sr^+(g) + OH(g)$ is fairly close to that for SrOH (96.7 $kcal·mol^{-1}$).[2] This suggests that the bonding in these two molecules may be quite similar. Thus bond distances are assumed to be the same as those adopted for SrOH(g).[2] The vibrational frequencies are assumed to be similar to those adopted for SrOH(g).[2] The ground state quantum weight is assumed to be the same as that of KOH (g).[2]

Enthalpy of Formation

Wagman[1] and Cohen and Westburg[2] have reviewed the data which leads to the enthalpy of formation for HO_2(g). We adopt the value suggested by Wagman,[1] $\Delta_f H°(HO_2, g, 298.15\ K) = 0.5 \pm 2.0\ kcal \cdot mol^{-1}$. Gurvich *et al.*[3] have also critically reviewed many of the same sources and have adopted the same value for the enthalpy of formation. The analysis by Wagman[1] follows.

Kochubei and Moin[4] made a kinetic determination of the enthalpy of formation of the HO_2 radical by studying the bimolecular radical formation reactions (forward only) $HX(g) + O_2(g) = HO_2(g) + X(g)$, where X = Cl, Br, and I. The basic rate data are not given for this study. However, Wagman corrected their reported results by a small amount due to the improperly used term designated as $\bar{T} d\Delta H/dT$). In the recalculation, the reported E_t–E_r values were used as the $\Delta_r H°$ at the stated mean temperature. Hence the $\Delta_f H°(298.15\ K)$ for HO_2(g) from this study is about 0.7 $kcal \cdot mol^{-1}$.

Calculations for $\Delta_f H°(HO_2, g)$ were also made using the reaction $H_3^+(g) + O_2(g) = HO_2^+(g) + H_2$ (g). For this reaction, Fennelly, *et al.*[5] obtained $\Delta_r H°(0\ K) = -0.05 + 0.07\ kcal \cdot mol^{-1}$. Kim *et al.*,[6] from rate constants for the above, obtain $\Delta_r G°(298.15\ K) = -0.41\ kcal \cdot mol^{-1}$. Estimating $\Delta S°(298.15\ K)$ to be $+0.40\ cal \cdot K^{-1} \cdot mol^{-1}$, and hence $\Delta_r H°(298.15\ K) = -0.3 \pm 0.10\ kcal \cdot mol^{-1}$. The best value is $\Delta_r H°(298.15\ K) = -0.2 \pm 0.2\ kcal \cdot mol^{-1}$. Quantum mechanical calculations of the energy of H_3^+ have been made by a number of people.[7,8] Using the results of Duben and Lowe[8] and ionization potential of HO_2 from Foner and Hudson,[9] Wagman obtained $\Delta_f H°(HO_2, g) = 1.1\ kcal \cdot mol^{-1}$. This yields $\Delta_f H°(HO_2, g, 298.15\ K) = 0.4\ kcal \cdot mol^{-1}$.

An additional calculation can be obtained from the ionization and appearance potentials for HO_2 from H_2O_2. Recent measurements by photoionization at NBS yield $\Delta_r H° = 348.7 \pm 0.2\ kcal \cdot mol^{-1}$ for $H_2O_2(g)$, $H_2O_2 + e^- = HO_2{}_+(g) + H^+ + 2\,e^-$. Combining with the ionization potential of HO_2(g) leads to $\Delta_r H°$ for $H_2O_2(g) = HO_2(g) + H(g)$ and $\Delta_f H°(HO_2, g, 298.15\ K) = 0.6\ kcal \cdot mol^{-1}$.

In these last two calculations, the principal uncertainty lies in the value for the ionization potential of HO_2 reported by Foner and Hudson.[9] However the general consistency of the various paths indicates that a reasonable value for $\Delta_f H°(HO_2, g, 298.15\ K)$ is $0.5 \pm 2.0\ kcal \cdot mol^{-1}$.

Heat Capacity and Entropy

The vibrational frequencies adopted are those determined by Paukert and Johnston[11] from infrared absorption measurements on gas phase HO_2. Matrix studies of HO_2 yielded similar results.[12–14] The bond lengths and bond angles are taken from the microwave spectroscopic study of Beers and Howard.[15] Other measurements are in agreement with these values.[11, 14, 16, 17]

The energy separation between the ground and lowest excited electronic state was determined by Freedman and Jones.[18] Their measurements also yield $I_A I_B I_C$ to be $1.090 \times 10^{-117}\ g^3 \cdot cm^6$ and $\nu_3 = 983\ cm^{-1}$ for the $^2A'$ state. This indicates that the structure of this excited state is quite similar to the ground state; thus, for convenience in calculating the entropy and heat capacity, the vibrational frequencies and moments of inertia of the excited state are taken to be the same as the ground state. For the ground electronic state, the principal moments of inertia are: $I_A = 0.1375 \times 10^{-39}$, $I_B = 2.5088 \times 10^{-39}$ and $I_C = 2.6463 \times 10^{-39}\ g \cdot cm^2$.

Enthalpy of Formation

Jordan[1] estimated the dissociation energy of PH(g) as 70.44 kcal·mol^{-1} using a semiempirical theoretical method. The corresponding value for the enthalpy of formation $\Delta_f H°(298.15\ K)$ is 60.6 ± 8 kcal·mol^{-1}.

Heat Capacity and Entropy

Jordan[1] predicted five electronic levels ($X^3\Sigma$, $A^1\Delta$, $B^1\Sigma$, $D^1\Pi$, $E^1\Sigma$) based on the reported value[2] of 29560 cm^{-1} for the $C^3\Pi$ level (this level is designated $A^3\Pi$ by Herzberg.[2] Several qualitative spectroscopic investigations of PH(g) have been reported and are in general accord with the predictions of Jordan.[1] Ishaq and Pearse[3] reported the values of the rotational constant B_e and the fundamental vibrational frequency ω_e. The value of α_e is calculated from the Morse potential function. The bond distance is calculated from B_e. The value of the anharmonic vibrational term $\omega_e x_e$ is estimated from the relation $\omega_e x_e = \omega_e^2/(4D° + 2\omega_e)$.

Enthalpy of Formation

$\Delta_f H°(298.15\ K)$ is calculated from the dissociation energy of PbH(g) reported by Gaydon.[1]

Heat Capacity and Entropy

Ground state configuration and spectroscopic data were obtained from Herzberg.[2] Electronic levels and multiplicity were estimated by comparison with those for PbF(g).

Enthalpy of Formation

The previous JANAF[1] selection for $\Delta_f H°$(HS, g, 298.15 K) was Mackle's[2] estimate of 34.6 ± 4 kcal·mol^{-1} which he derived from the average of three independent determinations. Of these, the uncertainty can be reduced in the determination involving the calculation of $\Delta H_f°$(HS, g, 298.15 K) from $\Delta_f H°(H_2S, g, 298.15\ K)$, the ionization potential of HS(g), and the appearance potential of HS^+(g) from H_2S(g). A summary of previous work on the ionization potential is given below. From the spectroscopic and photoionization work we arrive at a value of $\Delta_f H°(0\ K)$ for the reaction $H_2S(g) = HS(g) + H(g)$ of 89.02 ± 1.5 kcal·mol^{-1}. Using the appropriate thermal functions for each of the species (see tables for H_2S(g), HS(g), and H(g)[1]) and the selected enthalpies of formation of H_2S(g) of −4.90 ± 2 kcal·mol^{-1} (see H_2S(g) table[1]) and H(g) of 52.103 ± 0.001 kcal·mol^{-1},[8] one obtains 33.3 ± 1.2 kcal·mol^{-1} for $\Delta_f H°$(HS, g, 298.15 K) versus Mackle's[2] values of 33.7 ± 3 kcal·mol^{-1} for this determination. The new value is preferred because it is based on photoionization rather than electron impact studies.

Source	Method	Potential(eV)
$HS(g) \rightarrow HS^+(g) + e^-(g)$:		
Morrow[3]	Rydberg Extrapolation	10.40 ± 0.03
Palmer and Loosing[4]	Electron Impact	10.5 ± 0.1
$H_2S(g) \rightarrow HS^+(g) + H(g) + e^-(g)$		
Dibeler and Liston[5]	Photoionization	14.27 ± 0.04[†]
Dibeler and Rosenstock[6]	Electron Impact	14.43 ± 0.1
Palmer and Lossing[4]	Electron Impact	14.43 ± 0.1
Neuert and Clasen[7]	Electron Impact	15.2 ± 0.5

[†]The uncertainty given by the authors was doubled because the threshold value was not corrected to absolute zero.

Heat Capacity and Entropy*

Calculations were made using the vibrational and rotational constants for the respective electronic levels from Rosen.[12] Comparison of the results of the more exact treatment of Haar *et al.*[13] with those given in the previous JANAF[1] calculations (both used the same molecular constants for the ground state) suggests errors in our calculations are negligible above 400 K. Below this, they can be appreciable. In particular, it is recommended that 0.045 kcal·mol^{-1}, 0.012 cal·K^{-1}·mol^{-1} and −0.028 cal·K^{-1}·mol^{-1} be added to our values of $H°(0\ K) - H°(298.5\ K)$, $S°(298.15\ K)$, and $C_p°(298.15\ K)$. These errors result from dealing with the ground state ($X^2\Pi_i$) as two separate electronic states separated by 377.01 cm^{-1}.

The thermodynamic functions are calculated using first–order anharmonic corrections to Q_r^i and Q_v^i in the partition function $Q = Q_t \Sigma Q_r^i Q_v^i g_i \exp(-c_2\epsilon_i/T)$. The National Bureau of Standards prepared this table[9] by critical analysis of data existing in 1972. Using molecular constants and $\Delta_f H°$ selected by NBS,[9] we recalculate the table in terms of 1973 fundamental constants,[10] 1975 atomic weights[11] and current JANAF reference states for the elements.

Enthalpy of Formation

Verma[4] has derived an upper limit for the dissociation energy of 24680 cm^{-1} (70.6 $kcal·mol^{-1}$) from predissociation in the $B\ ^2\Sigma^+$ state. Hildenbrand[5] has applied an ionic–covalent correction to the linear Birge–Sponer extrapolation and obtained $D_0^\circ = 70\ kcal·mol^{-1}$. Rao and Lakshman[6] have estimated the ground state dissociation energy of 24040 cm^{-1} (68.7 $kcal·mol^{-1}$) from an evaluation of the potential energy curves and Franck–Condon factors. This last number, $D_0^\circ = 68.7\ kcal·mol^{-1}$, is adopted and may be compared with the average per-bond atomization energy of SiH_4(g) of 75.7 $kcal·mol^{-1}$. The $D_0^\circ/\Delta_{at}H°(0\ K)$ ratio is 0.227. For SiF/SiF the ratio is 0.230, for SiCl/$SiCl_4$ it is 0.233 and for SiI/SiI_4 it is 0.245.[7] The adopted D_0° and JANAF auxiliary data[7] lead to $\Delta_f H°(0\ K) = 89.6\ kcal·mol^{-1}$. The allowed error of ±2 $kcal·mol^{-1}$ includes the upper limit value of D_0°.

Heat Capacity and Entropy

The observed and estimated electronic levels are taken from Herzberg *et al.*,[1] Jordan,[2] and Bollmark *et al.*[3] as indicated. Wirsam's[8] ab initio self-consistent-field and configuration-interaction calculations predicted the electronic level for the $^4\Sigma^-$ state at 6430 and 8275 cm^{-1} respectively. Substitution of 6430 cm^{-1} for the adopted Jordan estimate of 21510 cm^{-1} increases the derived entropy starting near 700 K; at 6000 K, the entropy is 0.85 $cal·K^{-1}·mol^{-1}$ higher.

The rotational and vibrational constants are those selected by Rosen.[9] The ground state is treated as two distinct levels because of the splitting of the ground state as expressed by the spin coupling constant ($A = 142.83\ cm^{-1}$). This approximation gives slightly biased results at lower temperatures which are allowed for in the ±0.05 $cal·K^{-1}·mol^{-1}$ error assigned to $S°(298.15\ K)$.

$B_e = 7.6603\ cm^{-1}$ $\alpha_e = 0.2096\ cm^{-1}$ $r_e = 1.499$ Å

Enthalpy of Formation

According to Douglas and Lutz[1] the A state must have an extremely shallow potential curve since the observed first vibrational quantum is only $\Delta_{1/2}G' = 390.2\ cm^{-1}$. Since no other levels were observed they estimated ω_e' and $\omega_e x_e'$ for the A state from $\Delta_{1/2}G'$, α_e' and B_e'. From the estimated ω_e' and $\omega_e x_e'$ they obtained a dissociation limit of 1180 cm^{-1}. Thus, the dissociation limit of the A state is likely to lie between 390 and 1180 cm^{-1}, on this basis Douglas and Lutz select 780 ± 600 cm^{-1}. Since SiH⁺ can correlate with normal products $Si^+(^2P)$ and $H(^2S)$ in both the X and A states these are assumed to be the products. Thus, the dissociation energy of the ground state to these 294.626 ± 1.0 $kcal \cdot mol^{-1}$[2] we obtain $\Delta_f H°(SiH^+, g) = 272.5 \pm 2.7\ kcal \cdot mol^{-1}$, which is adopted. This gives an ionization potential of 182.9 $kcal \cdot mol^{-1}$ (7.93 eV) with the JANAF value for SiH.[2]

Heat Capacity and Entropy

The electronic levels and vibrational and rotational constants are all from Douglas and Lutz.[1]

ω_e = [1400] cm^{-1} $\omega_e x_e$ = [19] cm^{-1} σ = 1
B_e = [5.1] cm^{-1} α_e = [0.09] cm^{-1} r_e = [1.821] Å

Enthalpy of Formation

$\Delta_f H°(0\ K)$ was estimated as 123.7 $kcal·mol^{-1}$ by Gordon.[1] $\Delta_f H°(298.15\ K)$ is then calculated.

Heat Capacity and Entropy

Molecular constants were estimated by Gordon.[1] r_e is calculated from the relationship $r_e = (16.858778/\mu B_e)^{1/2}$ Å.

$H = 5.224 \times 10^{-5} - 7.240 \times 10^{-6}Y + 9.619 \times 10^{-7}Y^2 - 4.838 \times 10^{-8}Y^3$

$L = 6.70 \times 10^{-8} - 1.426 \times 10^{-8}Y + 1.388 \times 10^{-9}Y^2$

$v_{max} = 14$, $J_{max} = 38 - 32v/v_{max}$

Normalized rotational statistical weights = 1/4 (even J) and 3/4 (odd J)

Ground State Configuration: $^1\Sigma_g^+$ $r_e = 0.7414$ Å

Enthalpy of Formation

Zero by definition. Refer to the monatomic hydrogen gas table for a discussion of the dissociation energy.

Heat Capacity and Entropy

These are calculated by direct summation over vibration–rotation energy levels of the electronic ground state. We performed the direct summation with an extended version of a program written by W. H. Evans and provided through cooperation of D. D. Wagman, both of the U. S. National Bureau of Standards. Contributions of excited states (T_0 >90000 cm^{-1}) are negligible at 6000 K. Polynomials G, B, D, and H are our fits of data from Stoicheff,[1] Herzberg and Howe[2] and Rank *et al.*[3,4] We estimate polynomial L such that our approximation[5,6] for the infinite series F yields high-J rotational levels in reasonable agreement with the theoretical values of Waech and Bernstein.[7] Maximum deviations in our F values are about ±400 cm^{-1}; these occur near $1 \le v \le 4$ and $29 \le J \le 36$ which is far into the extrapolated region of F. Only about one-third of the vibration–rotation levels have been observed spectroscopically and the theoretical calculations[7,6] provide the best available extrapolation to high values of J. Accuracy of the thermodynamic functions near 6000 K depends on this extrapolation and on the rotational cutoff procedure. We assume a linear approximation[5] for the limiting values (J_{max}) of rotational quantum number. Values in the J_{max} equation are estimated from theoretical calculations.[7,6] We omit the nuclear-spin contribution (R ln 4) to entroy and Gibbs energy function.

We adopt ortho–para "equilibrium" H_2 as the reference state at all temperatures. The previous JANAF reference state[8] referred to "normal" H_2 (75% ortho and 25% para). Our new reference state has signficiant changes in C_p°, S° and H°(T)–H°(298.15 K) at 100 K and slight changes at 200 K. Use of "equilibrium" H_2 as a reference state was proposed on the NBS H_2 table[9] which discusses three alternatives. Preferred alternatives are either "equilibrium" H_2 or "normal" H_2. "Normal" H_2 is the form always encountered except in low-temperature generation or catalytic ortho–para equilibrium. Use of "normal" H_2 involves a possible complication, depending on the choice of zero energy for ortho–H_2. If we chose the lowest allowed level (v=0, J=1 instead of v=0, J=0), then H°(298.15 K)–H°(0 K) would be 0.254 kcal·mol^{-1} less for "normal" than for "equilibrium" H_2. This would change the difference between $\Delta_f H^\circ(0\text{ K})$ and $\Delta_f H^\circ(298.15\text{ K})$ for all species involving hydrogen.[8,10] No such change would occur if we chose the lowest level (v=0, J=0) as the energy zero for ortho–H_2. "Equilibrium" H_2 is the form which parallels most substances, i.e., those maintaining equilibrium among all rotational levels.[9]

JANAF values and uncertainties at 298.15 K are the same as those selected by CODATA.[10] Previous thermochemical tables based on direct-summation calculations of Woolley *et al.*[6] include that of Gurvich *et al.*[11] and that of NBS–JANAF.[9,8] Differences of the new JANAF values from the NBS table are greatest near 5300 K, reaching maximum of 0.005 cal·K^{-1}·mol^{-1} in S° and 0.018 kcal·mol^{-1} in H°(T)–H°(298.15 K). Differences from Gurvich *et al.* at 6000 K are 0.006 cal·K^{-1}·mol^{-1} in S° and 0.030 kcal·mol^{-1} in H°(T)–H°(298.15 K). Errors larger than these differences arise from uncertainty in extrapolation of the rotational levels.

Ground State Configuration: $^2\Sigma_g^+$ $r_e = 1.057$ Å[1,13]

Enthalpy of Formation

The adopted value for the enthalpy of formation of H_2^+(g), $\Delta_f H^\circ$(0 K) = 355.727 ± 0.001 kcal·mol^{-1}, is based on the ionization potential of H_2(g) determined by Herzberg and Jungen.[1] These authors studied in high resolution absorption two Rydberg series of ortho– and para–hydrogen which converge to the $X^2\Sigma_g^+$ ground state of H_2^+(g). This ionization potential, IP = 124417.2 ± 0.4 cm^{-1} is recommended by Rosenstock[2] as the definitive value. The IP or $\Delta_f H^\circ$(0 K) value is converted to a $\Delta_f H^\circ$(298.15 K) value for H_2^+(g) by including JANAF[3] enthalpy differences, H°(0 K)–H°(298.15 K), for H_2^+(g), H_2(ref) and e$^-$(ref). $\Delta_f H^\circ$(298.15 K) should not be interpreted as a room–temperature ionization threshold due to inclusion of these enthalpies and to threshold effects noted by Rosenstock *et al.*[4]

Rosenstock *et al.*[4] had earlier recommened IP = 16.4256 eV (124418.4 cm^{-1}) based on the spectroscopic studies of Takezawa[5] and Herzberg.[6] In both studies the results were derived from extended Rydberg series. The more recent work of Herzberg and Jungen[1] provides a more accurate experimental value for the ionization potential due to the recognition of a pressure shift which was felt to be negligible in the earlier study.[6] The theroetical value, IP = 124417.3 cm^{-1}, is in excellent agreement (0.1 cm^{-1}) with our adopted value. This theoretical value, as discussed by Herzberg and Jungen,[1] is essentially the value of Hunter and Pritchard[7] with the relativistic and Lamb shift corrections of Jeziorski and Kolos[8] and the nonadiabatic correction of Bunker.[9]

Heat Capacity and Entropy

Thermodynamic functions for ortho–para "equilibrim" H_2^+ are calculated, as they were for H_2,[3] by direct summation over energy levels of the electronic ground state. We use 1973 fundamental constants[10] in an extended version of a computer program written by W. H. Evans and provided by D. D. Wagman of the U. S. National Bureau of Standards. Excited electronic states are neglected because they are either repulsive or too high lying[11] to contribute significantly. The electronic statistical weight is taken equal to the multiplicity since we neglect rotational splitting. Assumption of negligible splitting is common practice in theoretical calculation of H_2^+ energy levels[11–13] and it is justified thermodynamically by the small splitting constant.[14]

Coefficients of the energy–level polynomials are those derived from theoretical levels by Beckel *et al.*[13] New calculations[15] yield slightly different levels. The polynomials are confirmed by vibrational (v<3) and rotational (N<4) levels obtained from Rydberg spectra.[1] The value of L was derived[13] from a fit of theoretical levels with v = 0 to 14. Our adopted v_{max}, derived from the G polynomial, is one unit too low.[13,11] Limiting rotaitonal quantum numbers N_{max} are an approximation of values from theoretical calculations.[11,13] The resulting energy–level equations are very approximate near N_{max}, but they do closely reproduce thermodynamic functions[12,11] calculated directly from energy levels. More accurate equations do not signficantly improve the thermodynamic functions up to 6000 K.

We adopt functions closely reproducing those of Iorish and Yungman.[12] The effect of slightly different fundamental constants[12] is barely detectable. Our Gibbs–energy function deviates by less than 0.001 cal·K^{-1}·mol^{-1} at all temperatures. C_p°, S° and H° begin to deviate near 2000 K; differences range from +0.005 to −0.012 cal·K^{-1}·mol^{-1} in C_p°, ±0.001 cal·K^{-1}·mol^{-1} in S° and ±5 cal·K^{-1}·mol^{-1} in H°. C_p° of Patch and McBride[11] is slightly lower at 4000 to 6000 K but well within the probable uncertainty. Due to the high thermal energy (−20% of D_0° at 6000 K), C_p° depends on the number of levels included in the summation. We follow the published references[11,12] which include contributions from quasibound levels lying above D_0°. At 6000 K these levels contribute 0.42 cal·K^{-1}·mol^{-1} to C_p° and 0.05 cal·K^{-1}·mol^{-1} to the Gibbs–energy function.

Enthalpy of Formation

The heat of formation at 0 K for H_2^-(g) is based on the electron affinity value derived from a Rydberg–Klein–Rees configuration–interaction calculation.[1] This study by Sharpe[1] led to EA (H_2) = −2.5 eV. Using auxiliary data,[2] we calculate $\Delta_f H^\circ$(0 K) kcal·mol^{-1} and $D_0^\circ(H_2^-)$ = 28.2 ± 10 kcal·mol^{-1}; the latter value assumes dissociation into ground state H(g) and H^-(g). This adopted EA(H_2) value is suggested to be the more reliable value of eight studies considered by Rosenstock *et al.*[3]

In terms of molecular orbitals, the ground state for H_2^-(g) is the $(1s\sigma_g)^2(2p\sigma_u)$ $2\Sigma_u^+$ state involving two bonding electrons and one antibonding electron.[4] We would expect, however, the ground state to be $(1s\sigma_g)^2(2s\sigma_u)$. As stated by Massey,[4] we should expect only a weakly–bound molecule as compared with H_2(g) for which the ground state has no electron in an antibonding orbital. Our calculated EA(H_2) value is consistent with this viewpoint. Further discussion of the H_2^-(g) ion may be found in Massey.[4]

$\Delta_f H^\circ$(0 K) is converted to $\Delta_f H^\circ$(298.15 K) by use of JANAF[2] enthalpies, H°(0 K)–H°(298.15 K), for H_2(g), H_2^-(g), and e^-(ref). $\Delta_f H^\circ$(298.15 K) should not be interpreted as a room temperature electron affinity due to inclusion of these enthalpies and to threshold effects discussed by Rosenstock *et al.*[3]

Heat Capacity and Entropy

The vibrational constants for H_2^-(g) are estimated to be the same as in the isoelectronic species He_2^+.[5] The internuclear distance is estimated to be ~8% larger than that for He_2^+(g). The same relationship appeared to exist for the (N_2^-, NO, O_2^+) isoelectronic series. B_e is calculated from r_e whereas α_e is calculated assuming a Morse function for the ground state.

The ground and excited electronic states are discussed in detail by Massey.[4] No excited state contributions are included in this calculation. By assuming the same force constant to exist for H_2^- as in He_2^+, we would calculate ω_e = 3384 cm^{-1}. This leads to an entropy at 298.15 K which is 0.06 cal K^{-1}·mol^{-1} smaller than our adopted value. The vibrational constants derived by Comer and Read[5] for some resonant state of H_2^- suggests ω_e values of 1500, 2300, and 2800 cm^{-1}. Thus, the ω_e value is very uncertain.

Ground State Quantum Weight: [1] σ = [2]
Point Group: [C_{2v}]
Bond Distances: Si–H = [1.49] Å Si–I = [2.44] Å
Bond Angles: H–Si–H = [111]° I–Si–I = [110]°
Product of the Moments of Inertia: $I_A I_B I_C$ = [3.067590 × 10^{-112}] $g^3◀cm^6$

Enthalpy of Formation

$\Delta_f H°(298.15\ K)$ is estimated by linear interpolation between the values[1] of SiI_4(g) and SiH_4(g). There are no experimental $\Delta_f H°$ data for SiH_3I, SiH_2I_2 and $SiHI_3$. Data for the iodomethanes[2] have a surprising progression (SiH3I, g);[1] they are of doubtful use in predicting $\Delta_f H°$ of the iodosilanes. We conclude, as did Hunt and Sirtl,[3] that the available data justify only linear interpolation of $\Delta_f H°$.

Heat Capacity and Entropy

The molecular structure is estimated by comparison with SiH_3I, SiI_4 and the various bromo–, chloro– and flurosilanes.[1] The principal moments of inertia are: I_A = 10.2009 × 10^{-39}, I_B = 168.8775 × 10^{-39} and I_C = 178.0688 × 10^{-39} $g·cm^2$.

Five vibrational frequencies are estimated by comparison with the dihalo–, monohalo– and trihalosilanes[1] plus $SiHBrI_2$ and $SiHClI_2$.[4] Frequencies ν_1, ν_2 and ν_8 were observed in gas–phase infrared spectra,[5] while ν_7 was observed in liquid–phase infrared spectra.[6]

We neglect excited states and assume the electronic ground state to be a singlet. We expect that contributions from excited states should be unimportant, as discussed on the tables for SiH_3Br and SiH_2Cl_2.[1]

Enthalpy of Formation

$\Delta_f H°(K_2(OH)_2, g, 298.15\ K)$ is calculated from the enthalpy of dimerization, $\Delta_{dim} H°(298.15\ K) = -45.3 \pm 3.0\ kcal \cdot mol^{-1}$, and the enthalpy of formation of the monomer, $\Delta_f H°(KOH, g, 298.15\ K) = -55.6 \pm 3.0\ kcal \cdot mol^{-1}$. Refer to the KOH(g) table for details.

Heat Capacity and Entropy

A key to the molecular structure of $K_2(OH)_2$(g) is provided by the work of Buchler *et al.*[1] which involves the electric deflection of molecular beams of $Cs_2(OH)_2$(g) and $Na_2(OH)_2$(g). Their results indicate that these dimers are nonpolar which implies a planar structure for at least the M_2O_2 part of the molecule. The three models proposed thus far for the dimeric alkali metal hydroxides each incorporate this planar configuration for the alkali and oxygen atoms. Bauer *et al.*[2] proposed a model consisting of a square planar configuration for the alkali and oxygen atoms with two hydrogen bonded bridges between the oxygens and hydrogens. Schoonmaker and Porter[3] adopted the square planar model for the M_2O_2 configuration but did not allow for hydrogen bonding. Berkowitz *et al.*[4] proposed a model for $Li_2(OH)_2$(g) which consisted of a trans configuration with hydrogens above and below the plane of a rhombus formed by the lighium and oxygen atoms, the O–Li–O bond angle being 100°. The adopted molecular structure for $K_2(OH)_2$(g) is similar to the model of Berkowitz *et al.*[4] but with the O–K–O bond angle equal to 90°. The K–O–H bond angle is assumed equal to 110°. The K–O bond distance is estimated as being 10% longer than that in KOH(g). The O–H bond distance is estimated to be the same as in H_2O(g). The principal moments of inertia are: $I_A = [17.5192] \times 10^{-39}$, $I_B = [38.5520] \times 10^{-39}$, and $I_C = [55.6426] \times 10^{-39}\ g \cdot cm^2$.

The first six vibrational frequencies are taken equal to those for dimeric K_2F_2(g) (See K_2F_2(g) table), and the remaining O–H stretching and bending modes are estimates taken from the work of Berkowitz *et al.*[4]

Enthalpy of Formation

The reaction between water vapor and condensed lithium oxide has been investigated as a function of temperature and water pressure by means of such techniques as mass spectrometry[1,2] and transpiration.[3] At low water pressures (<0.01 Torr) in the temperature range 780–900 K, Schoonmaker and Porter[1] observed only Li^+ and $LiOH^+$ ion species in the mass spectrum of the reaction products. The precursor of these two ions was assumed to be monomeric LiOH. Berkowitz *et al.*[2] in a more extensive mass spectrometric study of the Li_2O(cr)–H_2O(g) equilibrium detected not only monomeric and dimeric LiOH in the vapor phase, but also trace amounts of trimer ($Li_3(OH)_3$). Their work covered the temperature range 1100–1400 K at water pressures of 0.04 and 0.16 Torr. Absolute equilibrium constants were determined for the dimerization reaction, 2 LiOH(g) = $Li_2(OH)_2$(g), by calibrating the mass spectrometer in units of pressure. This was accomplished by measuring the water pressure externally and simultaneously monitoring the intensity of the H_2O^+ peak. In an attempt to investigate the same equilibrium at water pressures inaccessible to mass spectrometry, Berkowitz–Mattuck and Buchler[3] used the transpiration method. Their work covered water pressures of 4.58 and 19.5 Torr at 1095 and 1145 K. An analysis of these equilibrium data are summarized below.

Source	Reaction[a]	Method	T/K	Data Points	$\Delta_f H°$(298.15 K), kcal·mol^{-1} 2nd law	3rd law	Drift cal·K^{-1}·mol^{-1}	$\Delta_f H°$(298.15 K) kcal·mol^{-1}
Berkowitz, *et al.*[2]	A	Mass Spec.	1119–1352	9 [b]	−57.2	−63.8 ± 1.4	−5.4 ± 2.8	−175.8 ± 4.0
Berkowitz–Mattock	B	Transp.	1095, 1145	2		12.7		−188.2 ± 4.0

[a]Reactions: A) 2 LiOH(g) = $Li_2(OH)_2$(g) B) H_2O(g) + Li_2O(cr) = $Li_2(OH)_2$(g)

[b]One point rejected due to failure of a statistical test.

It seems most likely that the equilibrium data of Berkowitz–Mattuck and Buchler[3] are in error, since no satisfactory compromise in the flow rates of the inert carrier gas could be found such that saturation was achieved while eliminating thermal diffusion effects. Under these conditions the simple equations relating partial pressures to the masses transported during the transpiration experiment are now longer valid. Furthermore, the authors assumed that under the conditions of their experiment only dimer LiOH would be formed. The work of Berkowitz *et al.*[2] clearly establishes the existence of a trimer at water pressures some 100 times lower than those employed by Berkowitz–Mattuck and Buchler.[3]

Trends in the dimerization energies for the higher alkali metal hydroxides, as well as for the dimeric alkali fluorides and chlorides, suggest that the enthalpy of dimerization for LiOH from the work of Berkowitz *et al.*[2] may be slightly high. Such a comparison results in $\Delta_f H°$(dimerization, 298.15 K) values in the range −(52–61) kcal·mol^{-1}. Further support for a lower value comes from the mass spectral work of Porter and Schoonmaker.[1] They investigated the reaction of H_2O(g) with a mixture of condensed Li_2O–Na_2O. From the reported ion current intensities for the various ions found in the reaction products we calculate, $\Delta_{dim}H°$(NaOH, g, 298.15 K) −$\Delta_{dim}H°$(LiOH, g, 298.15 K) = 5.3 kcal·mol^{-1}. This value yields $\Delta_{dim}H°(298.15\ K) = -56.0 \pm 5$ kcal·mol^{-1}for LiOH(g) when used in combination with the adopted value for NaOH(g).[4] A high enthalpy of dimerization from the mass spectral work of Berkowitz *et al.*[2] is easily reconciled in terms of nonequilibrium measurements. Based upon these findings, we adopt $\Delta_{dim}H°(298.15\ K) = -58.0 \pm 5.0$ kcal mol for LiOH(g). Combining this result with the enthalpy of formation for LiOH(g),[4] that for the dimer is $\Delta_f H°(Li_2(OH)_2, g, 298.15\ K) = -170.0 \pm 8$ kcal·mol^{-1}

Heat Capacity and Entropy

The molecular structure of $Li_2(OH)_2$(g) is assumed identical to that adopted for the higher alkali metal hydroxide dimers. It consists of a planar configuration for the lithium and oxygen atoms with the O–Li–O bond angle equal to 90°. The hydrogen atoms are placed in a trans–configuration above and below the plane of the rhombus formed by the lithium and oxygen atoms. The Li–O–H bond angle is assumed equal to 110°. The Li–O bond distance is estimated as being 10% longer than in LiOH(g). The O–H bond distance is estimated to be the same as in H_2O(g). The principal moments of inertia are: $I_A = [3.7044 \times 10^{-39}]$, $I_B = [9.2519 \times 10^{-39}]$, and $I_C = [12.5268 \times 10^{-39}]$ g·cm^2.

The first six vibrational frequencies are estimated by comparison with calculated[5] and experimental[4,6] frequencies for Li_2F_2(g). In the estimation it is assumed that the bulkier OH group would tend to reduce the frequencies of $Li_2(OH)_2$(g) relative to those for Li_2F_2(g). The remaining OH stretching and bending frequencies are estimates from the work of Berkowitz *et al.*[2]

PREVIOUS: June 1971 (1 atm) CURRENT: June 1971 (1 bar)

$S°(298.15\ K) = 31.091 \pm 0.84\ J \cdot K^{-1} \cdot mol^{-1}$

$\Delta_f H°(0\ K) = -68.00 \pm 9.2\ kJ \cdot mol^{-1}$
$\Delta_f H°(298.15\ K) = -76.15 \pm 9.2\ kJ \cdot mol^{-1}$

Enthalpy of Formation

The enthalpy of hydrolysis of MgH_2(cr) was measured by Sinke and Stull.[1] The value of $\Delta_f H°(298.15\ K)$ was calculated to be -19.1 ± 2 kcal·mol^{-1}. From the decomposition pressure measurements for MgH_2(cr) reported by Ellinger[2] and Stampfer *et al.*[3] the values of $\Delta_f H°(298.15\ K)$ for MgH_2(cr) were found to be -17.9 ± 1.0 and -17.7 kcal·mol^{-1}, respectively. The value used was the average of these three.

Heat Capacity and Entropy

The low temperature heat capacities (25–300 K) were measured by Sinke and Hildenbrand.[4] Above 300 K the $C_p°$ values were estimated by comparison with those for MgF_2(cr). $S°(298.15\ K)$ is obtained from Sinke and Hildenbrand[4] using $S°(25\ K) = 0.037$ cal·K^{-1}·mol^{-1} (extrap.).

Decomposition Data

$T_{dcm} = 560$ K is estimated from the value of $\Delta_f G°$ in the table.

$S°(298.15\ K) = 63.243\ J·K^{-1}·mol^{-1}$

$\Delta_f H°(0\ K) = -915.64 \pm 2.1\ kJ·mol^{-1}$
$\Delta_f H°(298.15\ K) = 924.66 \pm 2.1\ kJ·mol^{-1}$

Enthalpy of Formation

The adopted value is an average of −221.10 and −220.86 kcal·mol^{-1} obtained from $\Delta_f H°(298.15\ K) = 9.08$ and 8.84 kcal·mol^{-1} for the dehydration reaction $Mg(OH)_2(cr) = MgO(cr) + H_2O(l)$, using auxiliary data.[13, 14] The two values correspond to natually occurring brucite and to synthetic $Mg(OH)_2$ prepared from MgO by hydration at 177 °C under a steam pressure of about 9 atm. The enthalpies of reaction are derived from studies of Taylor and Wells[1] on the enthalpys of solution of various samples of $Mg(OH)_2$and MgO in aqueous HCl. These studies show that the enthalpy of dehydration is quite dependent on the nature of the MgO sample; e.g., values for synthetic $Mg(OH)_2$ vary monotonically from 9.79 to 8.84 kcal·mol^{-1} for MgO ignited at temperatures from 450 to 1425 °C, respectively. The authors ascribe this difference primarily to increase in particle size at the higher ignition temperatures. More recent work[15] suggests that the difference is caused by crystalline disorder rather than particle size alone. We have adopted the results at 1425 °C since they are reasonably consistent with the high temperature samples on which the JANAF enthalpy of formation for MgO is based. The uncertainty is estimated as ±0.5 kcal·mol^{-1}.

Shomate and Huffman[2] have confirmed the enthalpy of solution of MgO (ignited at 1000°C) within about 0.3 kcal·mol^{-1}. Their value may be combined with the enthalpy of solution for synthetic $Mg(OH)_2$, determined under similar conditions by Torgeson and Sahama[3] to obtain $\Delta_r H° = 8.85$ kcal·mol^{-1} for the dehydration reaction. At the other extreme, the enthalpy of solution data of Giauque and Archibald[4] lead to $\Delta_r H° = 9.74$ kcal·mol^{-1}; however, this value corresponds to MgO ignited at 350 °C. The MgO sample was microcrystalline and had significant excess $C_v°$ as suggested by Giauque and Archibald[4] and later confirmed by data of Barron *et al.*[5] Giauque and Archibald[4] intentionally used the microcrystalline form which would be similar to the product in their decomposition pressure measurements (190 and 212 °C). Thus, it is not surprising that 3rd law analysis of their decomposition pressures yields essentially the same enthalpy of formation as their solution data (see summary below). Decomposition data at higher pressures have been reported by Fyfe[6] Roy and Roy[7] Kennedy[8] Zhabrova and Kadenatsi[9] and Berg and Rassonskaya.[10] These data do not significantly affect the enthalpy of formation, however, because of uncertainties in the attainment of equilibrium and in reduction to standard state values.

[a]Prepared by reaction of KOH with $MgCl_2$(aq) at 210 °C, rather than by hydration of MgO.
[b]For $Mg(OH)_2(cr) = MgO(cr) + H_2O(g)$ rather than $Mg(OH)_2(cr) = MgO(cr) + H_2O(l)$.

Heat Capacity and Entropy

The low temperature heat capacities are from the measurements (22–321 K) of Giauque and Archibald[4] who used a synthetic, macrocrystalline sample of magnesium dihydroxide prepared by reacting KOH with aqueous $MgCl_2$ at 210°C. The entropy is derived from the heat capacities starting with $S°(20\ K) = 0.027\ cal·K^{-1}·mol^{-1}$ from a T^3 extrapolation. $S°(298.15\ K) = 15.11\ cal·K^{-1}·mol^{-1}$ compares favorably with 15.09 cal·K^{-1}·mol^{-1} given by Giauque and Archibald.[4] The drop calorimeter enthalpy measurements (350–699 K) of King *et al.*[11] are used to derive heat capacities above 298.15 K. They used a ground sample of natural brucite, which analyzed 98.77% $Mg(OH)_2$. Their published data are corrected for impurities and to one atmosphere total pressure. The low and high temperature heat capacities were joined smoothly by mathematical curve fitting techniques. Heat capacities above 700 K are obtained by extrapolation.

The reference temperature for the enthalpy measurements (393–667 K) of Lashchenko and Kompanskii[12] is uncertain. Their values appear to be near those of King *et al.*[11] up to around 550 K; above 550 K their values average about 5% lower than those of King *et al.*[11]

Decomposition Data

T_{dcm} = 542.2 K is calculated as the temperature at which the fugacity of $H_2O(g)$ is 1 atm for the reaction $Mg(OH)_2(cr) = MgO(cr) + H_2O(g)$.

Enthalpy of Formation

Alexander, *et al.*[1] determined the temperature dependence of the equilibrium constant for the reaction $MgO(cr) + H_2O(g) = Mg(OH)_2(g)$ in the range of 1650 to 2020 K by measuring vapor densities using a transpiration technique. The data are presented graphically and are represented by a linear equation. With auxiliary data,[2] analysis of the equation yields a 2nd law $\Delta_r H°(298.15\ K) = 67.1\ kcal \cdot mol^{-1}$ and a 3rd law $\Delta_f H°(298.15\ K) = 64.70\ kcal \cdot mol^{-1}$ with a drift of $-1.3\ cal \cdot K^{-1} \cdot mol^{-1}$. From the 3rd law heat of reaction, the adopted $\Delta_f H°(298.15\ K) = -136.80\ kcal \cdot mol^{-1}$ is calculated. An uncertainty of $\pm 8.0\ kcal \cdot mol^{-1}$ is assigned to allow for the uncertainty shown in the vapor density measurements and for the uncertainty in the entropy.

The enthalpy of dissociation listed by Jackson[6] leads to $\Delta_f H°(Mg(OH)_2, g, 298.15\ K) = -140.74\ kcal \cdot mol^{-1}$. Another recent compilation[7] lists $\Delta_f H°(298.15\ K) = -134\ kcal \cdot mol^{-1}$.

Based on the adopted $\Delta_f H°(298.15\ K) = -136.80 \pm 8\ kcal \cdot mol^{-1}$, $\Delta_r H°(0\ K) = 188.6\ kcal \cdot mol^{-1}$ is calculated for the reaction $Mg(OH)_2(g) = Mg(g) + 2\ OH(g)$.

Heat Capacity and Entropy

The analogy between gaseous mono– and dihydroxides and gaseous mono– and dihalides, particularly the mono– and difluorides, has been recognized.[3-6] The O–Mg–O bond angle is assumed to be the same as the F–Mg–F bond angle;[2] the Mg–O–H bond is considered to be linear as in MgOH.[2] The Mg–O bond distance is estimated to be slightly larger, 0.02 Å, than the Mg–F distance in MgF_2[2] after noting the close similarity in the bond distance of the alkali metal fluorides and hydroxides. The O–H bond distance is taken to be the same as in water.[2]

The vibrational frequencies are estimated to be the same as in MgF_2[2] (O–Mg–O symmetrical and asymmetrical stretch, and bend) and as in MgOH[2] (O–H stretch and Mg–O–H bend). The principal moments of inertia are: $I_A = 0.3029 \times 10^{-39}$, $I_B = 18.8449 \times 10^{-39}$, and $I_C = 19.1478 \times 10^{-39}\ g \cdot cm^2$.

Jackson[6] has used a different molecular configuration and different vibrational frequencies to estimate $S°(298.15\ K) = 63.829\ cal \cdot K^{-1} \cdot mol^{-1}$. We assign an uncertainty of $\pm 3.0\ cal \cdot K^{-1} \cdot mol^{-1}$ to the adopted entropy.

Enthalpy of Formation

The enhanced volatility of metallic molybdenum and molybdenum trioxide in the presence of water vapor at high temperatures has been investigated by several workers[1,2,3] using transpiration techniques. Glemser and Haeseler[1] and Bulten[2] have shown that the major volatilization reaction of the oxide is:

A. $MoO_3(cr) + H_2O(g) = MoO_2(OH_2)(g)$.

For the reaction of metallic molybdenum with water vapor, Belton and Jordan[3] reported the existence of $MoO_2(OH)_2(g)$ according to the equilibrium:

B. $Mo(cr) + 4H_2O(g) = MoO_2(OH)_2(g) + 3H_2(g)$.

2nd and 3rd law analyses of these equilibrium data are summarized below.

Source	Reaction	T/K	Data Points	$\Delta_f H°$(298.15 K), kcal·mol^{-1} 2nd law	3rd law	Drift cal·K^{-1}·mol^{-1}	$\Delta_f H°$(298.15 K) kcal·mol^{-1}
Glemser and Haeseler[1]	A	873–963	Equation	36.2	31.9 ± 0.3	−4.2	−204.0 ± 0.5
Buiten[2]	A	673–773	Equation	30.0	32.2 ± 0.3	3.6	−203.7 ± 0.5
Belton and Jordan[3]	B	1473–1773	Equation	30.1	28.6 ± 0.1	−0.1	−202.6 ± 0.3

The adopted value, $\Delta_f H°(MoO_2(OH)_2, g) = -203.4 \pm 1.0\ kcal·mol^{-1}$, is an average of these three results.

Heat Capacity and Entropy

The assumed tetrahedral structure for $MoO_2(OH)_2$ is from Jordan.[4] The O–H bond length and H–O–Mo bond angle are assumed to be the same as for $H_2O(g)$. The Mo–O bond length is from the compilation of Sutton[5] and assumed to be the same as for Ag_2MoO_4. Principal moments of inertia are: $I_A = 23.7897 \times 10^{-39}$, $I_B = 25.3843 \times 10^{-39}$, and $I_C = 25.4477 \times 10^{-39}\ g·cm^2$.

The vibrational frequencies are estimated by comparison with those for $H_2SO_4(g)$[6,7] and are adjusted to give $S°(MoO_2(OH)_2, g) = 137.4$ cal·K^{-1}·mol^{-1} at 1600 K. This entropy value is derived from a 2nd law analysis of the equilibrium data for reaction *B* reported by Belton and Jordan.[3]

Point Group: C_{2v} $\sigma = 2$
Bond Distance: N–H = 1.024 Å
Bond Angle: H–N–H = 103°
Product of the Moments of Inertia: $I_A I_B I_C = 0.0085 \times 10^{-117}\ g^3·cm^6$

Enthalpy of Formation

Direct kinetic studies[1-5] onthe decomposition of hydrazine, $N_2H_4(g) = 2\ NH_2(g)$, give activation energies which suggest $\Delta_f H°(NH_2, 298.15\ K) \leq 40\ kcal·mol^{-1}$. [The kinetic rates are discribed by k_d for the the forward reaction and k_r for the reverse reaction]. The pre–exponential factor suggests $k_r \sim 10^7 - 10^8$ l/(mol s). This is exceptionally slow for a radical combination reaction[6] and is at variance with the most recent direct measurements of $k_r = 10^{10.8}$ l/(mol s) (300 K, 1500 mmHg)[7] and $k_r = 10^{9.4}$ l/(mol s) (300 K, 10 mmHg).[8] A possible explanation for this discrepancy is that the hydrazine decomposition studies have been carried out in the energy dependent region.[9,10] This has been confirmed on the basis of RRKM calculations. With $\Delta_f H°(298.15\ K) = 40\ kcal·mol^{-1}$, it is not possible to simultaneously reproduce the measured forward (k_d) and backward (k_r) rates by orders of magnitude. With a value of $\Delta_f H°(298.15\ K) = 45.5\ kcal·mol^{-1}$, all of the rate data can be fitted to a factor of three. For higher values of $\Delta_f H°(298.15\ K)$, the discrepancy increases.

Data on the thermal decomposition of benzylamine from toluene–carrier studies[2,11] yield $\Delta_f H°(298.15\ K) = 36\ kcal·mol^{-1}$. This technique, however, has consistently yielded erroneous rate paramters.[12] Using their very low pressure pyrolysis technique, Golden *et al.*[13] find $\Delta_f H°(NH_2, 298.15\ K) = 47.2\ kcal·mol^{-1}$. This is in reasonable agreement with the recommended value.

Heat Capacity and Entropy

The bond distance and angle are from the electronic absorption spectrum as summarized by Herzberg.[14] The vibrational frequencies are obtained from Herzberg[14] and from matrix–isolation studies of Milligan and Jacox.[15]

The National Bureau of Standards prepared this table[16] by critical analysis of data existing in 1972. Using $S°$, $C_p°$ and $\Delta_f H°$ selected by NBS,[16] we recalculate the table in terms of current JANAF reference states for the elements.

Ground State Quantum Weight: 1 $\sigma = 2$
Point Group: C_{2v}
Bond Distances: N–H = [1.014] Å; N–N = [1.23] Å
Bond Angle: H–N–N = [100]°
Product of the Moments of Inertia: $I_A I_B I_C$ = [1.3981 × 10^{-117}] $g^3·cm^6$

Enthalpy of Formation

The standard enthalpy of formation, $\Delta_f H°(N_2H_2, g, 298.15\ K)$ = 50.9 $kcal·mol^{-1}$, was calculated from the appearance and ionization potentials of di–imide reported by Foner and Hudson[1] using the JANAF $\Delta_f H°(N_2H_4, g, 0\ K)$ = 26.1 $kcal·mol^{-1}$ in calculation. For example:

	$\Delta_r H°(0K)$
$N_2H_4(g) \rightarrow N_2H_2^+ + H_2(g) + e$	11.0 ± 0.2 $cal·K^{-1}·mol^{-1}$
$N_2H_2(g) \rightarrow N_2H_2^+ + e$	9.85 ± 0.1 $cal·K^{-1}·mol^{-1}$
$N_2H_4(g) \rightarrow N_2H_2(g) + H_2$	1.15 ± 0.2 $cal·K^{-1}·mol^{-1}$
	26.5 ± 5 $kcal·mol^{-1}$

From the above enthalpy of formation and that for NH(g) in the JANAF Tables 12–31–65, one can calculate a N–N bond energy of 109.4 ± 5 $kcal·mol^{-1}$ at 0 K. This is in agreement with the N–N bond in molecules such as N_2F_2.

Heat Capacity and Entropy

The bond distances and angle were obtained from a quantum–mechanical calculation by Wheland and Chen.[2] The principal moments of inertia are: I_A = [0.3114] × 10^{-39}, I_B = [1.9689] × 10^{-39} and I_C = [2.2803] × 10^{-39} $g·cm^2$.

Since there are 12 valency electrons in N_2H_2, Walsh[3] has predicted a bent ground state, existing in either a cis or a trans configuration for diimide. Blau and Hochheimer[4] have measured the infrared spectrum of diimide which was frozen in a cold trap as one of the decomposition products of N_2H_4. The spectrum of the solid N_2H_2 at liquid nitrogen temperature agrees with the predicted non–linear planar structure, and the molecule N_2H_2 appears mainly in cis form. They have also assigned six fundamental vibrational frequencies for cis H_2H_4(s) which have been adopted here for gaseous cis N_2H_2. Blau and Hochheimer also observed two gas phase bands (1277–1314 and 3050–3190 cm^{-1}). Rosengren and Pimentel[5] have observed these bands in matrix isolation studies. They assigned ν_1 or ν_4 = 3074 cm^{-1} and ν_3 = 1279 cm^{-1} which are in satisfactory agreement with the selected frequencies.

Enthalpy of Formation

Mass spectrometric studies of the vapors in equilibrium with NaOH(l)[1,2] and mixed NaOH–KOH condensed phases,[3,4] along with a study of the vapor composition by a molecular beam velocity analysis technique,[5] have established the importance of monomeric and dimeric species in the temperature range 573–1050 K. Absolute partial pressures for the monomer and dimer calculated from peak intensity data by Porter and Schoonmaker[3] are analyzed by the 3rd law method with JANAF Gibbs energy functions[6] to give a enthalpy of dimerization of −50.0 $cal·mol^{-1}$ at 298.15 K. Schoonmaker and Porter[4] also calculated differences in the Gibbs energies of dimerization for several alkali metal hydroxide pairs from peak intensity data on mixed systems. A 3rd law analysis of the Gibbs energy data for the NaOH–KOH system leads to a difference in their enthalpies of dimerization of −6.0 $kcal·mol^{-1}$ at 298.15 K. Based upon the adopted value for KOH(g), $\Delta_{dim}H°$(= −45.3 $kcal·mol^{-16}$, we derive $\Delta_{dim}H°$(= −51.3 $kcal·mol^{-1}$ for NaOH(g). For the reaction 2 NaOH(g) = $Na_2(OH)_2$(g), we adopt a mean of these two results, $\Delta_{dim}H°(298.15\ K) = -50.7 \pm 3.0\ kcal·mol^{-1}$. Combining this result with the adopted enthalpy of formation for NaOH(g),[6] that for the dimer is $\Delta_f H°(Na_2(OH)_2, g, 298.15\ K) = -145.2 \pm 6.0\ kcal·mol^{-1}$.

Heat Capacity and Entropy

A key to the molecular structure of $Na_2(OH)_2$(g) is provided by the work of Buchler *et al.*[7] which involves the electric deflection of molecular beams of $Cs_2(OH)_2$(g) and $Na_2(OH)_2$(g). Their results indicate that these dimers are nonpolar which implies a planar structure for at least the M_2O_2 part of the molecule. The three models proposed thus far for the dimeric alkali metal hydroxides each incorporate this planar configuration for the alkali and oxygen atoms. Bauer *et al.*[8] proposed a model consisting of a square planar configuration for the alkali and oxygen atoms with two hydrogen bonded bridges between the oxygens and hydrogens. Schoonmaker and Porter[4] adopted the square planar model for the M_2O_2 configuration but did not allow for hydrogen bonding. Berkowitz *et al.*[9] proposed a model for $Li_2(OH)_2$(g) which consisted of a trans–configuration with hydrogens above and below the plane of a rhombus formed by the lithium and oxygen atoms, the O–Li–O bond angle being 100°. The adopted molecular structure for $Na_2(OH)_2$(g) is similar to the model of Berkowitz *et al.*[9] but with the O–Na–O bond angle equal to 90°. The Na–O–H bond angle is assumed equal to 110°. The Na–O bond distance is estimated as being 12% longer than that in NaOH(g). The O–H bond distance is estimated to be the same as in H_2O(g). The principal moments of inertia are: $I_A = [14.0843] \times 10^{-39}$, $I_B = [18.1898] \times 10^{-39}$, and $I_C = [31.8478] \times 10^{-39}\ g·cm^2$.

The first six vibrational frequencies are estimated by comparison with those for other alkali metal fluorides and hydroxides. The remaining O–H stretching and bending modes are estimates taken from the work of Berkowitz *et al.*[9]

$S°(298.15\ K) = 69.950 \pm 0.079\ J \cdot K^{-1} \cdot mol^{-1}$ $\Delta_f H°(298.15\ K) = -285.830 \pm 0.042\ kJ \cdot mol^{-1}$

Enthalpy of Formation

The adopted enthalpy of formation and uncertainty are taken from the CODATA recommended values[1] which are, in turn, based on calorimetric measurements by Rossini[2] and King and Armstrong.[3]

Heat Capacity and Entropy

The adopted C_p° data from 273.15 to 373.15 K are taken from the very accurate calorimetric measurements of Osborne *et al.*[4] Heat capacity data taken from the recent equation of state formulation of Haar *et al.*[5] agree with the adopted data to within 0.06% above 320 K with deviations up to 0.12% being noted near 305 K. In the latter region the experimental C_p° data go through a single smooth minimum while data derived from the equation of state exhibit an incipient double minimum behavior. These deviations are very small and would lead to nearly negligible differences in the thermochemical functions.

We have made an approximate extrapolation of C_p° (l, p=1 bar) to temperatures where water is unstable with respect to vaporization by using data derived from Haar's equation of state formulation.[5] From 373.15 to 390 K the adopted C_p°(1 bar) data were taken directly from Haar *et al.*[5] while from 400 to 450 K the adopted C_p° data were derived by taking advantage of the constant difference of 0.0090 $cal \cdot K^{-1} \cdot mol^{-1}$ between C_p(10 bar) and C_p°(1 bar) observed between 320 to 390 K using the data of Haar *et al.*[5] Above 450 K the C_p(100 bar) data[5] were adjusted by a similar procedure although the difference is no longer constant. The C_p° adjustment from 10 bar to 1 bar is less than 0.05% while that from 100 bar to 1 bar ranges from 0.9 to 1.2%.

The adopted value of $S°(298.15\ K) = 16.718 \pm 0.019\ cal \cdot K^{-1} \cdot mol^{-1}$ is taken from the CODATA recommended value.[1] This was calculated by CODATA from the entropy of the ideal gas with appropriate corrections for real gas behavior and vaporization.

Vaporization Data

The boiling point and enthalpy of vaporization to the real gas at p=1 bar are taken from the work of Haar *et al.*[5] see the H_2O (liquid–real gas at p=1 bar) JANAF Table[6] for further details. The enthalpy of vaporization, $\Delta_{vap}H°$, to the ideal gas is calculated as $\Delta_{vap}H° = \Delta_f H°(g) - \Delta_f H°(l, p=1\ bar)$ using JANAF data.[6] The temperature and enthalpy of vaporization at f=1 bar represent the calculated values at the point where $\Delta_r G° = 0$ for the process $H_2O(l) \rightarrow H_2O$(ideal gas). Thus, these values represent boiling to the (hypothetical) ideal vapor at a fugacity of 1 bar.

Enthalpy of Formaton

The adopted value of $\Delta_f H°(298.15\ K)$ is that recommended by CODATA[1] and was calculated by CODATA from the heat of formation of liquid water at 298.15 K using vaporization data given by Keenan *et al.*[2] The enthalpy of atomization, $\Delta_{at}H°(0\ K) = 219.352 \pm 0.026$ $kcal \cdot mol^{-1}$, is calculated using auxiliary JANAF data.[3]

Heat Capacity and Entropy

The adopted heat capacity and entropy data below 2000 K, which are for water with the natural isotopic abundance, are taken from recent calculations by Woolley.[4] Wooley has done detailed calculations on the thermodynamic functions of light isotopic water ($^1H_2{}^{16}O$) and then corrected those to functions appropriate for water of natural isotopic abundance. Below 240 K, his calculation was a direct summation over rotational levels of the group vibrational state, with small additions above 130 K for the ν_2=1 vibrational level. Above 240 K, individual vibrational partition functions were summed to obtain the total partition function. During this summation the molecule was treated as a rigid rotator with modified corrections of Stripp–Kirkwood and centrifugal effect types, guided by the behavior found for the vibrational ground state. Details are given by Woolley.[4]

Between 2000 and 5000 K we adopt $C_p°$ data calculated by Friedman and Haar[5] for light isotopic water, after a small correction. Our correction consists of adding 0.021 $cal \cdot K^{-1} \cdot mol^{-1}$ to Friedman and Haar's $C_p°$ data. This correction arises from the constant difference of 0.021 ± 0.001 $cal \cdot K^{-1} \cdot mol^{-1}$ between Woolley's $C_p°$ data (natural abundance) and Friedman and Haar's $C_p°$ data (light isotopic water) in the temperature range 1300–2000 K. Above 5000 K, we have linearly extrapolated Friedman and Haar's corrected $C_p°$ data.

Below 2000 K there is good agreement among thermodynamic functions given by Woolley[4], Friedman and Haar[5] and Glushko *et al.*[6] Above 2000 K the $C_p°$ data from references[5] and[6] begin to deviate significantly; at 4000 and 6000 K the differences $[C_p°^{6} - C_p°^{5}]$ are 0.57 and 1.07 $cal \cdot K^{-1} \cdot mol^{-1}$, respectively. Woolley is working on extending his calculations to higher temperature[7] and his initial results[4] yield $C_p°$ values slightly higher than[5] but not nearly so high as.[6]

Values of $S°(298.15\ K)$ and $H°(298.15\ K) - H°(0\ K)$ in the present table are in excellent agreement with CODATA values[1] of 45.106 ± 0.01 $cal \cdot K^{-1} \cdot mol^{-1}$ K) and 2.368 ± 0.002 $kcal \cdot mol^{-1}$, respectively.

$S°(298.15\ K) = 69.950 \pm 0.079\ J \cdot K^{-1} \cdot mol^{-1}$ $\Delta_f H°(298.15\ K) = -285.830 \pm 0.042\ kJ \cdot mol^{-1}$

Enthalpy of Formation

Refer to the H_2O(l, p=1 bar) table for details.[1]

Heat Capacity and Entropy

The adopted heat capacity data in the liquid region are taken from the very accurate calorimetric measurements of Osborne *et al.*[2] The adopted heat capacity data for the real gas at one bar pressure are taken from the recent equation of state formulation of Haar *et al.*[3] Refer to the JANAF Table for H_2O(l, p=1 bar) for details concerning the entropy.

Phase Data

Our table refers to the real fluid existing at the standard–state pressure of 1 bar. Since this pressure is below the critical pressure of water [P_c = 217.6 bar at T_c = 647.14 K][4] there is a first order transition at the normal boiling point. Therefore, this is a two phase (liquid real gas) table for the real fluid at p=1 bar.

Fugacity and Fugacity Coefficient Data

At temperature T the fugacity f for the real gas at p=1 bar is given by $f = \exp[\Delta_f G(\text{real gas})\ \Delta_f G°(\text{ideal gas})/(RT)]$ using real gas data from this table and ideal gas data from from JANAF.[1] Since p=1 bar, the fugacity coefficient (f/P) is equal to the fugacity. The fugacity coefficient is 0.986 at 400 K and approaches 1 as temperature increases, indicating nearly ideal behavior at all temperatures.

Since the standard state for a gas is defined as the ideal gas at one bar pressure, the gas phase properties in this table are not standard state properties. The superscript zero, representing standard state, refers only to liquid-phase properties and not to gas-phase properties which are for the real gas at P=1 bar.

PREVIOUS: March 1979 (1 atm) CURRENT: March 1979 (1 bar)

S(298.15 K, 10 bar) = 69.946 ± 0.084 J·K^{-1}·mol^{-1} $\Delta_f H$(298.15 K, 10 bar) = −285.815 ± 0.042 kJ·mol^{-1}

Enthalpy of Formation

The enthalpy of formation of H_2O at 298.15 K and p=10 bar [$\Delta_f H$ H(298.15 K, 10 bar)] is derived from the CODATA[1] enthalpy of formation of the liquid at 298.15 K and 1 bar [$\Delta_f H°$(l, 298.15 K) = −68.315 ± 0.010 kcal·mol^{-1}] by addition of the enthalpy increment [H(298.15 K, 10 bar)–$H°$(298.15 K)]. The enthalpy increment is taken from the recent equation of state formation of Haar *et al.*[2] which yields enthalpy data at any temperature and pressure referenced to the triple point of water. The values of $\Delta_f H°$, $\Delta_f G°$ and log $K°$ in this table refer to formation of H_2O at p=10 bar from H_2 and O_2 in their standard reference states (ideal gas at a pressure of 1 bar).

Heat Capacity and Entropy

The adopted heat capacity data are taken from the recent equation of state formulation of Haar *et al.*[2] The entropy and enthalpy are obtained by appropriate integration of the C_p data and differ from entropy and enthalpy data calculated directly from the equiuccirclation of state formulation by less than 0.0001 cal·K^{-1}·mol^{-1} and 0.0001 kcal·mol^{-1}, respectively. The starting point for the entropy integration [S(298.15 K, 10 bar)] is obtained from the CODATA[1] entropy at standard conditions [$S°$(l, 298.15 K) = 16.7184 ± 0.019 cal·K^{-1}·mol^{-1})] by addition of the entropy increment [S(298.15 K, 10 bar) $S°$(298.15 K)]. The entropy increment is also taken from the equation of state formulation[2]

Phase Data

Our table refers to the real fluid phase existing at the nonstandard state pressure of 10 bar. Since this pressure is below the critical pressure of water [P_c = 217.6 bar at T_c = 647.14 K[3]] there is a first order transition at the boiling temperature. Therefore this is a two phase (liquid–real gas) table for the real fluid at p=10 bar.

Vaporization Data

The adopted boiling temperature (at 10 bar) and enthalpy of vaporization are taken from the equation of state formulation of Haar *et al.*[2]

Fugacity and Fugacity Coefficients Data

At temperature T the fugacity f of water at p=10 bar is given by f=$K/K°$ or f=exp[($\Delta_f G°$–$\Delta_f G°$)/(RT)], where K and $\Delta_f G°$ are values for H_2O(ideal gas, T).[4] The fugacity coefficient (f/P) at p = 10 bar is given by f/10. At p = 10 bar the fugacity coefficient is 0.99 at 800 K and the gas behaves in a nearly ideal manner above that temperature.

Enthalpy of Formation

The enthalpy of formation of H_2O at 298.15 K and p=100 bar [$\Delta_f H$(298.15 K, 100 bar)] is derived from the CODATA[1] enthalpy of formation of the liquid at 298.15 K and 1 bar [$\Delta_f H°$(l, 298.15 K) = −68.315 ± 0.10 kcal·mol^{-1}] by addition of the enthalpy increment [H(298.15 K, 100 bar)–$H°$(298.15 K)]The enthalpy increment is taken from the recent equation of state formulation of Haar *et al.*[2] which yields enthalpy data at any temperature and pressure referenced to the triple point of water. The values of $\Delta_f H*$, $\Delta_f G°$ and log $K°$ in this table refer to formation of H_2O at p=100 bar from H_2 and O_2 in their standard reference states (ideal gas at a pressure of 1 bar).

Heat Capacity and Entropy

The adopted heat capacity data are taken from the recent equation of state formulation of Haar *et al.*[2] The entropy and enthalpy are obtained by appropriate integration of the C_p data and differ from entropy and enthalpy data calculated directly from the equation of state formulation by less than 0.0012 cal·K^{-1}·mol^{-1} and 0.0008 kcal·mol^{-1}, respectively. The starting point for the entropy integration [S(298.15 K, 100 bar)] is obtained from the CODATA[1] entropy at standard conditions [$S°$(l, 298.15 K) = 16μccircl.7184 ± 0.019 cal·K^{-1}·mol^{-1}] by addition of the entropy increment [S(298.15 K, 100 bar)–$S°$(298.15 K)]. The entropy increment is also taken from the equation of state formulation.[2]

Phase Data

Our table refers to the real fluid phase existing at the nonstandard state pressure of 100 bar. Since this pressure is below the critical pressure of water [P_c = 217.6 bar at T_c = 647.14 K][3] there is a first order transition at the boiling temperature. Therefore this is a two phase (liquid real gas) table for the real fluid at p=100 bar.

Vaporization Data

The adopted boiling temperature (at 100 bar) and enthalpy of vaporization are taken from the equation of state formulation of Haar *et al.*[2]

Fugacity and Fugacity Coefficient Data

At temperature T the fugacity f of water at p=100 bar is given by f=$K/K°$ or f=exp[$\Delta_f G°$–$\Delta_f G°$)/(RT)], where K and $\Delta_f G°$ are values for H_2O(ideal gas).[4] The fugacity coefficient (f/p) at p=100 bar is given by f/100. At p=100 bar the fugacity coefficient is 0.99 at 1200 K and the gas behaves in a nearly ideal manner above that temperature.

Values of $\Delta_f H*$, $\Delta_f G*$, and Log K_f* in this table refer to formation of H_2O at P = 100 bar from H_2 and O_2 in their standard reference states (Ideal gas at a pressure of 1 bar).

PREVIOUS: March 1979 (1 atm) CURRENT: March 1979 (1 bar)

S(298.15 K, 500 bar) = 69.696 ± 0.167 J·K^{-1}·mol^{-1} $\Delta_f H$(298.15 K, 500 bar) = −285.014 ± 0.167 kJ·mol^{-1}

Enthalpy of Formation

The enthalpy of formation of H_2O at 298.15 K and p=500 bar [$\Delta_f H°$(298.15 K, 500 bar)] is derived from the CODATA[1] enthalpy of formation of the liquid at 298.15 K and 1 bar [$\Delta_f H°$(l, 298.15 K) = −68.315 ± 0.010 kcal·mol^{-1}] by addition of the enthalpy increment [H(298.15 K, 500 bar)–$H°$(298.15 K)]. The enthalpy increment is taken from the recent equation of state formulation of Haar *et al.*[2] which yields enthalpy data at any temperature and pressure referenced to the triple point of water. The values of $\Delta_f H°$, $\Delta_f G°$ and log $K°$ in this table refer to formation of H_2O (real fluid at p = 500 bar) from H_2 and O_2 in their standard reference states (ideal gas at a pressure of 1 bar).

Heat Capacity and Entropy

The adopted heat capacity data are taken from the recent equation of state formulation of Haar *et al.*[2] The entropy and enthalpy are obtained by appropriate integration of the C_p data and differ from entropy and enthalpy data calculated directly from the equation of state formulation by less than 0.0004 cal·K^{-1}·mol^{-1} and 0.0002 kcal·mol^{-1}, respectively. The starting point for the entropy integration [S(298.15 K, 500 bar)] is obtained from the CODATA[1] entropy at standard condtions [$S°$(l, 298.15 K) = 16.7184 ± 0.019 cal·K^{-1}·mol^{-1}] by addition of the entropy increment [S(298.15 K, 500 bar)–$S°$(298.15 K)]. The entropy increment is also taken from the equation of state formulation.[2]

There is a significant maximum in the C_p(500 bar) data which rises to 40.2 cal·K^{-1}·mol^{-1} near 730 K. In this temperature region the density is varying rapidly but continuously with temperature; the maximum in the C_p data is due to a change in sign of the derivative of the density temperature curve. These same density changes are also responsible for large effects on intermolecular interaction as measured by the fugacity coefficient which changes from 0.22 at 600 K to 0.69 at 800 K (refer below).

Phase Data

Our table refers to the fluid phase existing at the nonstandard state pressure of 500 bar. Since 500 bar exceeds the critical pressure of water (P_c = 217.6 bar at T_c = 647.14 K)[3] the properties of the fluid vary continuously with temperature. Thus our table is a single phase table for the compressed fluid. No first order phase transition occurs, even though labels such as compressed liquid and dense gas are sometimes used for the regions below and above T_c.

Fugacity and Fugacity Coefficient Data

At temperature T the fugacity f of water at p = 500 bar is given by $f = K/K°$ or f=exp[$(\Delta_f G° - \Delta_f G°)/(RT)$], where K and $\Delta_f G°$ are values for H_2O(ideal gas).[4] The fugacity coefficient (f/p) at p =500 bar is given by f/500.

Values of $\Delta_f H$*, $\Delta_f G$*, and Log K_f* in this table refer to formation of H_2O at P = 500 bar from H_2 and O_2 in their standard reference states (Ideal gas at a pressure of 1 bar).

PREVIOUS: March 1979 (1 atm) CURRENT: March 1979 (1 bar)

S(298.15 K, 5000 bar) = 69.627 ± 0.209 $J \cdot K^{-1} \cdot mol^{-1}$ $\Delta_f H$(298.15 K, 5000 bar) = −278.394 ± 0.418 $kJ \cdot mol^{-1}$

Enthalpy of Formation

The enthalpy of formation of H_2O at 298.15 K and p=5000 bar [$\Delta_f H°$(298.15 K, 5000 bar)] is derived from the CODATA[1] enthalpy of formation of the liquid at 298.15 K and 1 bar [$\Delta_f H°$(l, 298.15 K) = −68.315 ± 0.010 $kcal \cdot mol^{-1}$] by addition of the enthalpy increment [H(298.15 K, 5000 bar)–$H°$(298.15 K)]. The enthalpy increment is taken from the recent equation of state formulation of Haar *et al.*[2] which yields enthalpy data at any temperature and pressure referenced to the triple point of water. The values of $\Delta_f H°$, $\Delta_f G°$ and log K in this table refer to formation of H_2O (real fluid at p=5000 bar) from H_2 and O_2 in their standard reference states (ideal gas at a pressure of 1 bar).

Heat Capacity and Entropy

The adopted heat capacity data are taken from the recent equation of state formulation of Haar *et al.*[2] The entropy and enthalpy are obtained by appropriate integration of the C_p data and differ from entropy and enthalpy data calculated directly from the equation of state formulation by less than 0.0002 $cal \cdot K^{-1} \cdot mol^{-1}$ and 0.0001 $kcal \cdot mol^{-1}$, respectively. The starting point for the entropy integration [S(298.15 K, 5000 bar)] is obtained from the CODATA[1] entropy at standard condtions [$S°$(l, 298.15 K) = 16.7184 ± 0.019 $cal \cdot K^{-1} \cdot mol^{-1}$] by addition of the entropy increment [S(298.15 K, 5000 bar)–$S°$(298.15 K)]. The entropy increment is also taken from the equation of state formulation.[2]

There are two rather small maximum in the C_p(5000 bar) data near 420 and 780 K.

Phase Data

Our table refers to the fluid phase existing at the nonstandard–state pressure of 5000 bar. Since 5000 bar exceeds the critical pressure of water (P_c = 217.6 bar at T_c = 647.14 K)[3] the properties of the fluid vary continuously with temperature. Thus our table is a single phase table for the compressed fluid. No first–order phase transition occurs, even though labels such as compressed liquid and dense gas are sometimes used for the regions below and above T_c.

Fugacity and Fugacity Coefficient Data

At temperature T the fugacity f of water at p = 5000 bar is given by $f = K/K°$ or $f = \exp[(\Delta_f G° - \Delta_f G°)/(RT)]$, where K and $\Delta_f G°$ are values for H_2O(ideal gas).[4] The fugacity coefficient (f/p) at p=5000 bar is given by f/5000.

PREVIOUS: December 1960 (1 atm) CURRENT: December 1960 (1 bar)

$S°(298.15\ K) = [97.069 \pm 8.4]\ J \cdot K^{-1} \cdot mol^{-1}$
$T_{fus} = 783.15 \pm 15\ K$

$\Delta_f H°(0\ K)$ = Unknown
$\Delta_f H°(298.15\ K) = -968.89 \pm 9.2\ kJ \cdot mol^{-1}$
$\Delta_{fus} H° = 21.020 \pm 2.1\ kJ \cdot mol^{-1}$

Enthalpy of Formation

The adopted $\Delta_f H°(298.15\ K) = -231.57 \pm 2.2\ kcal \cdot mol^{-1}$ is obtained from the enthalpy of formation adopted for the liquid[1] minus enthalpy of melting and the enthalpy difference of the liquid and the crystal between the melting point and 298.15 K. The dissociation pressure measurements by Johnston[2] and by Tamaru and Shiomi[3] span the melting point, but there is not a definite break in the log P vs 1/T curve at the melting point. The temperatures of the dissociation pressures determined by Sano[4] are all below the melting point. For 2nd and 3rd law analysis, using auxiliary data from the JANAF Thermochemical Tables,[1] the dissociation pressures below the melting point are considered to pertain to the equilibrium $Sr(OH)_2(cr) = SrO(cr) + H_2O(g)$.

Source	Data Points	T/K	$\Delta_r H°(298.15\ K)$, kcal·mol⁻¹ 2nd law	3rd law	Drift cal·K⁻¹·mol⁻¹	$\Delta_f H°(298.15\ K)$ kcal·mol⁻¹
Johnston[2]	4	703–776	18.7	31.65 ± 1.06	17.5 ± 1.4	−230.9 ± 1.9
Tamaru and Shiomi[3]	10	667–782	28.0	31.50 ± 0.42	4.9 ± 0.3	−230.8 ± 1.2
Sano[4]	5	613–743	26.0	31.27 ± 0.75	7.6 ± 0.2	−230.6 ± 1.6

These three 3rd law values for $\Delta_f H°$(cr, 298.15 K) are in excellent agreement, are in reasonable agreement with the adopted value, and are closer to another recent evaluation[5] of −229.2 kcal·mol⁻¹ than is the adopted value. The route taken to derive the adopted value is presently preferred because dissociation pressure measurements of the liquid are judged to be better than those of the solid.

Heat Capacity and Entropy

The heat capacities are derived from a curve fit of the drop calorimeter enthalpy measurements of Powers and Blalock,[6] (545–783 K), extrapolated and forced through zero relative enthalpy at 273.15 K. The change in heat capacity with temperature is larger than it is for the other alkaline earth dihydroxides.[1] There appears to be no definite explanation for this. The purity of the $Sr(OH)_2$ sample, as indicated by total alkalinity, did change more during the enthalpy measurement than other samples in the same report.[6] The total alkalinity of the $Sr(OH)_2$ sample changed from 99.80 to 94.1% while for $Ba(OH)_2$ the change was 100.4 to 99.81%, for NaOH the change was 99.97 to 99.46%, and for KOH the change was 100.00 to 98.68%.[6] The known existence of crystalline allotropy in some of the alkaline earth halides and hydroxides suggests this possibility for $Sr(OH)_2$ crystal also.

The adopted entropy, $S°(298.15\ K) = [23.2 \pm 2]\ cal \cdot K^{-1} \cdot mol^{-1}$, is calculated from Kelley's additive entropy constants for cations and anions.[7]

Fusion Data

From their drop calorimetry, Powers and Blalock[6] selected a melting point of 783.15 K where they derived $\Delta_{fus} H° = 5.23\ kcal \cdot mol^{-1}$. Our smoothing of their data leads to the adopted $\Delta_{fus} H° = 5.024 \pm 0.50\ kcal \cdot mol^{-1}$. Brcic and Jernejcic[8] determined a melting point of 771 K and Berggren and Brown,[9] 723 K. The latter dihydroxide sample contained 5 mole percent $SrCO_3$. $T_{fus} = 783.15 \pm 15$ K is adopted.

$S°(298.15\ K) = [108.739]\ J\cdot K^{-1}\cdot mol^{-1}$
$T_{fus} = 783.15 \pm 15\ K$

$\Delta_f H°(298.15\ K) = [-957.304]\ kJ\cdot mol^{-1}$
$\Delta_{fus} H° = 21.020 \pm 2.1\ kJ\cdot mol^{-1}$

Enthalpy of Formation

The adopted $\Delta_f H°(298.15\ K) = -228.8 \pm 1.7\ kcal\cdot mol^{-1}$ is the average of values derived from the 3rd law analysis of the dissociation pressure measurements of Johnston[1] and of Tamaru and Shiomi.[2] The data from both sources[1,2] span the melting point; only those data above the melting point are used for the 2nd and 3rd law analysis of the reaction $Sr(OH)_2(l) = SrO(cr) + H_2O(g)$.

Source	Data Points	T/K	$\Delta_r H°(298.15\ K)$, kcal·mol^{-1} 2nd law	3rd law	Drift cal·K^{-1}·mol^{-1}	$\Delta_f H°(298.15\ K)$ kcal·mol^{-1}
Johnston[1]	11[a]	806–1038	28.5	30.06 ± 0.28[b]	1.6 ± 0.4	−229.36 ± 1.1
Tamaru and Shioni[2]	6	880–942	30.9	29.93 ± 0.26[b]	−2.3 ± 0.2	−228.23 ± 1.1

[a]One point rejected due to a failure of a statistical test.
[b]Considering all of the data as liquid data (733–1038 K;[1] 667–942 K),[2] yields 3rd law enthalpies of reaction of 29.97 ± 0.48 kcal·mol^{-1} for[1] and 29.08 ± 0.16 kcal·mol^{-1} for[2] leading to standard state enthalpies of formation at 298.15 K of −229.27 ± 1.3 and −228.38 ± 1.0 kcal·mol^{-1}, respectively.

Heat Capacity and Entropy

$C_p°$ is derived from the drop ice calorimeter measurements of Powers and Blalock (789–1187 K)[4] and is assumed constant at 27.7 cal·K^{-1}·mol^{-1} over the range of 520 to 1600 K. A glass transition is assumed at 520 K below which $C_p°$ is that of the crystal. The entropy of 298.15 K is calculated from the value adopted for the crystal.[3]

Decomposition Data

T_{dcm} = 1017 K is calculated as the temperature at which the fugacity of $H_2O(g)$ is 1 atm for the reaction $Sr(OH)_2(l) = SrO(cr) + H_2O(g)$. Auxiliary data used in the calculations are from the JANAF Thermochemical Tables.[3]

Enthalpy of Formation

Dissociation energies for the reaction $Sr(OH)_2(g) = Sr(g) + 2\ OH(g)$ have been derived from flame spectral measurements.[1-3] Ryabova and Gurvich[1] believed the dominant reaction to be $Sr(g) + H_2O(g) = SrOH(g) + H(g)$ but they also considered the possibility that the reaction $Sr(g) + 2\ H_2O(g) = Sr(OH)_2 + 2\ H(g)$ was dominant and derived $D_0°$ = 180 ± 20 $kcal·mol^{-1}$. Sugden and Schofield[2] considered the dihydroxide to be the dominant product and derived $D_0°$ = 215 ± 12 $kcal·mol^{-1}$. Cotton and Jenkins[3] found both SrOH and $Sr(OH)_2$ to be present in significant amounts in fuel-rich hydrogen–oxygen–nitrogen flames and derived $D_0°$ = 202.2 ± 5 $kcal·mol^{-1}$. Cotton and Jenkins[3] recalculated the work of Ryabova and Gurvich[1] and of Sugden and Schofield[2] considering both SrOH and $Sr(OH)_2$ to be present and obtained the recalculated $D_0°$ values of 196 and 200 $kcal·mol^{-1}$, respectively.

A 3rd law analysis of the experimental equilibrium constants tabulated by Cotton and Jenkins[3] using current JANAF auxiliary data[4] leads to $D_0°$ = 204.8 $kcal·mol^{-1}$ which is 2.6 $kcal·mol^{-1}$ higher than the 202.2 $kcal·mol^{-1}$ derived by Cotton and Jenkins.[3] Applying this difference to the data of Ryabova and Gurvich[1] and of Sugden and Schofield[2] as recalculated by Cottonand Jenkins[3] gives $D_0°$ = 198.6 and 202 $kcal·mol^{-1}$, respectively.

For $Ba(OH)_2(g)$[4] the corrected dissociation energy of Ryabova and Gurvich,[4] $D_0°$ = 208.8 $kcal·mol^{-1}$, is in better agreement with the "adopted" value of 209.6 $kcal·mol^{-1}$, based on good Knudsen cell mass spectrometric measurements, than are the corrected dissociation energies of Sugden and Schofield or Cotton and Jenkins.[4] We adopt $D_0°$ = 198.6 $kcal·mol^{-1}$ for the dissociation of $Sr(OH)_2$ from which $\Delta_f H°(Sr(OH)_2)$ = −140.66 ± 6.0 $kcal·mol^{-1}$ is calculated.

The enthalpy of dissociation listed by Jackson[8] leads to $\Delta_f H°(Sr(OH)_2, g, 298.15\ K)$ = −143.82 $kcal·mol^{-1}$. Another recent compilation[9] lists $\Delta_f H°(298.15\ K)$ = −135 $kcal·mol^{-1}$.

Heat Capacity and Entropy

The analogy between gaseous mono- and dihydroxides and gaseous mono- and dihalides, particularly the mono- and difluorides, has been recognized.[5-8] The O–Sr–O bond angle is assumed to be the same as the F–Sr–F bond angle;[4] the Sr–O–H bond angle is considered to be linear as in SrOH.[4] The Sr–O bond distance is estimated to be slightly larger, 0.02 Å, than the Sr–F distance in SrF_2[4] after noting the close similarity in the bond distance of the alkali metal fluorides and hydroxides. The O–H bond distance is taken to be the same as in water.[4]

The vibrational frequencies are assumed to be the same as in SrF_2 (O–Sr–O symmetrical and asymmetrical stretch, and bend)[4] and as in SrOH (O–H stretch and Sr–O–H bend).[4] The principal moments of inertia are: $I_A = 7.3880 \times 10^{-39}$, $I_B = 19.3556 \times 10^{-39}$, and $I_C = 26.7436 \times 10^{-39}$ $g·cm^2$.

Jackson[8] has used a different molecular configuration and different vibrational frequencies to estimate $S°(298.15\ K)$ = 74.057 $cal·K^{-1}·mol^{-1}$. We assign an uncertainty of ±2.0 $cal·K^{-1}·mol^{-1}$ to the adopted entropy.

PREVIOUS: December 1975 (1 atm) CURRENT: December 1975 (1 bar)

$S°(298.15\ K) = 156.895 \pm 0.08\ J·K^{-1}·mol^{-1}$
$T_{fus} = 283.46 \pm 0.05\ K$

$\Delta_f H°(0\ K) = -811.969 \pm 0.67\ kJ·mol^{-1}$
$\Delta_f H°(298.15\ K) = -813.989 \pm 0.67\ kJ·mol^{-1}$
$\Delta_{fus} H° = 10.711 \pm 0.13\ kJ·mol^{-1}$

Enthalpy of Formation

The enthalpy of combustion, $\Delta_c H°(298.15\ K)$, of rhombic sulfur to aqueous sulfuric acid, S(cr, rhombic) + 3/2 O_2(g) + H_2O(l) = H_2SO_4 (n H_2O), has been determined by many investigators. Based on the reported combusion data, values of $\Delta_f H°(298.15\ K)$ for liquid H_2SO_4 are derived using tabulated enthalpy of solution and enthalpy of dilution data.[1,2] The value adopted, $\Delta_f H°(H_2SO_4, l, 298.15\ K) = -194.548 \pm 0.16$ kcal·mol^{-1}, is that recommended by NBS.[2] The uncertainty of ± 0.16 kcal·mol^{-1} not only accounts for the scatter in the combustion data but also the uncertainty arising from conversion of these data to be consistent with the current atomic weights and fundamental constants (~tens of calories/mol). An uncertainty of −0.08 kcal·mol^{-1} may exist due to the difference in the heat of formation of $SO_4^{=}$(aq) as reported by CODATA[11] and NBS.[2]

Good *et al.*[5]	H_2SO_4 (115 H_2O)	−143.85 ± 0.06	−194.521
Mansson and Sunner[6]	H_2SO_4 (115 H_2O)	−143.93 ± 0.07	−194.601

Heat Capacity and Entropy

The heat capacity has been measured experimentally[7] in the range 15–300 K and has been summarized by Giauque *et al.*[1] Above 300 K, the heat capacity values are derived from a nomograph constructed by Kharbanda[8] based on experimental data (0–300°C). These temperature–dependent values are corrected to current atomic weights, converted from IPTS–48 to IPTS–68, and adjusted graphically in the region 290–350 K so as to provide smoothly varying heat capacity values. In the region above 350 K, a linear dependence is assumed (as suggested from a least squares fit of the nomograph data); this linear dependence is used for extrapolation of the heat capacity values to 1000 K.

Other heat capacity studies on sulfuric acid and its aqueous solutions are too numerous to mention. However, a recent compilation[9] summarizes much of the work and shows that our adopted heat capacity values for sulfuric acid and its hydrates from room temperature to ~80°C are consistent with the available literature.

The entropy at 298.15 K is calculated by the appropriate integration of the crystal and liquid heat capacity values, $S°(15\ K) = 0.269$ cal·K^{-1}·mol^{-1} and addition of the entropy of melting.

Fusion Data

The melting point and enthalpy of melting have been measured calorimetrically by Rubin and Giauque.[7] The value for T_{fus} used by Giauque *et al.*[1] in their re evaluation and correlation of aqueous sulfuric acid properties was slightly different; the change was 0.07 K. Many other studies have also reported melting data but they are too numerous to mention.

Vaporization Data

$T_{vap} = 610$ K is the temperature at which the fugacity of H_2SO_4(g) is one atm for the reaction H_2SO_4(l) = H_2SO_4(g). $\Delta_{vap} H° = 13.9$ kcal·mol^{-1} is calculated as the difference in the respective $\Delta_f H°$ values at T_{vap}.

According to Luchinskii[10] the total pressure over H_2SO_4(l) reaches one atmosphere at 553 K with a vapor composition of 76.6 mole% SO_3, 22.6 mole% H_2SO_4, and 0.8 mole% H_2O.

Enthalpy of Formation

The vapor phase equilibria of the H_2SO_4, H_2O and SO_3 system have been determined by *PVT* studies by Bodenstein and Katayama[5] and Suvorov *et al.*[4] and by vapor pressure measurements by Luchinskii.[3] Using the reported equilibrium values (after correcting a few typographical errors) for the reaction $H_2SO_4(g) = H_2O(g) + SO_3(g)$, we calculate $\Delta_f H°(298.15\ K)$ using a 2nd and 3rd law analysis and auxiliary data.[6] The results are tabulated below. We adopt $\Delta_f H°(H_2SO_4, g, 298.15\ K) = -175.7 \pm 2\ kcal \cdot mol^{-1}$ which is the median of the three values derived from the 3rd law $\Delta_f H°(298.15\ K)$. The analysis of vaporization data of Thomas and Ramsey[1] and Abel[2] leads to $\Delta_f H°(298.15\ K)$ values within 2 $kcal \cdot mol^{-1}$ of our adopted value.

*Reactions: A) $H_2SO_4(l) = H_2SO_4(g)$ B) $H_2SO_4(g) = H_2O(g) + SO_3(g)$

Heat Capacity and Entropy

The molecular structure of $H_2SO_4(g)$ is assumed to be tetrahedral with differing bond lengths for S–O and S–OH. This adopted structure is consistent with the X-ray and electron diffraction studies on $H_2SO_4(cr)$ by Pascard[7] and Pascard–Billy,[8] respectively, and the X-ray scattering study on $H_2SO_4(l)$ by Weidner *et al.*[9] The latter study gave results which could be interpreted by models having point symmetry C_2 and C_{2v}. In both models, the sulfur–oxygen bond distance are equivalent within the experimental uncertainty. For the C_{2v} model, the O–S–O bond angles coincide with the tetrahedral angle. In the C_2 model these angles are split, but not as extremely as in $H_2SO_4(cr)$.[7,8] The OH distance and the S–O–H angle are taken from those for $H_2O(g)$. The principal moments of inertia are: $I_A = 14.9802 \times 10^{-39}$, $I_B = 17.0080 \times 10^{-39}$ and $I_C = 17.7023 \times 10^{-39}\ g \cdot cm^2$.

The vibrational frequencies are from the infrared studies of Chackalackal and Stafford[10] and the comparisons of Giguere and Savoie.[11] The infrared studies led to the assignement of nine vibrational frequencies while the remaining six were estimated[10] by comparison with the infrared frequencies for the crystal and Raman frequencies for the liquid.

PREVIOUS: September 1977 (1 atm) CURRENT: September 1977 (1 bar)

$S°(298.15\ K) = [144.766 \pm 25.1]\ J \cdot K^{-1} \cdot mol^{-1}$

$\Delta_f H°(0\ K)$ = Unknown

$\Delta_f H°(298.15\ K) = -1131.77 \pm 1.7\ kJ \cdot mol^{-1}$

Enthalpy of Formation

Spitsyn and Patsukova[1] have measured calorimetrically the enthalpy of reaction (1) and (2) at 298.15 K as -13.80 ± 0.01 and -13.05 ± 0.02 kcal·mol^{-1}, respectively. The reactions are given as follows:

(1) $WO_3(cr) + 2\ NaOH(66H_2O) \rightarrow Na_2WO_4(4200\ H_2O) + H_2O(l)$
(2) $H_2WO_4(cr) + 2\ NaOH(66H_2O) \rightarrow Na_2WO_4(4200\ H_2O) + 2\ H_2O(l)$

Combination of reactions (1) and (2) gives $\Delta_f H°(298.15\ K) = -0.75 \pm 0.04$ kcal·mol^{-1} for $WO_3(cr) + H_2O(l) \rightarrow H_2WO_4(cr)$, which leads to $\Delta_f H°(H_2WO_4, cr, 298.15\ K) = -270.5 \pm 0.4$ kcal·mol^{-1}.

To obtain WO_3(cr) in a form soluble in the calorimetric solution, Spitsyn and Patsukova dehydrated H_2WO_4(cr) at the relatively low temperature of 250°C. The resulting WO_3(cr) was a very fine lemon yellow powder which may have excess surface free energy compared with the JANAF standard state. The latter is WO_3 formed at high temperature in a calorimetric bomb. The actual enthalpy of formation of tungstic acid should be less negative if this effect is significant.

The previously accepted value (2, 3, 4) -280.2 ± 0.4 kcal·mol^{-1}, was based on the pressure temperature composition studies of Huttig and Kurre[5] for the WO_3 H_2O system. We suspect that the data do not correspond to equilibrium (see entropy section) for the reaction $H_2WO_4(cr) = WO_3(cr) + H_2O(g)$.

Heat Capacity and Entropy

$C_p°(300\ K) = 27.0$ cal·K^{-1}·mol^{-1} is estimated using Kopp's rule. Since the decomposition temperature of H_2WO_4(cr) is approximately 400 K, which is relatively low for hydrogen and oxygen to reach their maximum $C_p°$ contribution, we estimate $C_p°(400\ K) = 31.0$ cal·K^{-1}·mol^{-1} for H_2WO_4(cr).

The entropy, $S°(298.15\ K) = 34.6$ cal·K^{-1}·mol^{-1}, is estimated so that the decomposition pressure of water is one atmosphere at 120°C. This value is quite uncertain as suggested by comparison with the following estimates. A lower limit may be obtained from $S°(283.5\ K) = 26.8$ cal·K^{-1}·mol^{-1} for H_2SO_4(cr). Summation of the entropies for WO_3(cr) and H_2O(cr) [10.7 cal·K^{-1}·mol^{-1}] yields 28.8 cal·K^{-1}·mol^{-1}, and estimate which is somewhat larger than the lower limit. An upper limit may be obtained by assuming that the pressure of about 14 mm at 190 °C coresonds to equilibrium for the reaction $H_2WO_4(cr) = WO_3(cr) + H_2O(g)$. This pressure, baseiuccircld on the plateau in the temperature composition data of Huttig and Kurre[5] yields $S°(298.15\ K) = 46.5$ cal·K^{-1}·mol^{-1} when combined with the adopted $\Delta_f H°(298.15\ K)$ and JANAF auxiliary data. Since the estimate appears to be unreasonably large, we suggest that this region of the curve may correspond to the reaction $WO_3 \cdot 0.5\ H_2O(cr) = WO_3(cr) + 0.5\ H_2O(g)$. In contrast, the observed pressures[5] for samples having mole ratios (H_2O/WO_3) of 1.2 1.35 leads to $S°(298.15\ K) = 34$ cal·K^{-1}·mol^{-1}, if the reaction is $WO_3 \cdot H_2O(cr) = WO_3(cr) + H_2O(g)$.

Decomposition Data

$T_{dcm} = 393$ K is calculated as the temperature at which the fugucity of water is 1 atmosphere for the reaction $H_2WO_4(cr) \rightarrow WO_3(cr) + H_2O(g)$ approaches zero.

Spitsyn and Patsukova[1] observed that some dehydration of stoichiometric H_2WO_4(cr) occurs at temperature as low as 90°C. Thermal studies[6,7] on tungstic acid containing some exces water indicated the start of dehydration somewhere in the region of 60–120°C. These temperatures yield a lower limit for T_{dcm} on the presumption that the experiments correspond to a partial pressure of water of less than one atmosphere.

Enthalpy of Formation

The adopted enthalpy of formation, $\Delta_f H°(298.15\ K) = -216.5 \pm 1.0\ kcal·mol^{-1}$, is derived from equilibrium data[1-5] obtained by the transpiration method. The data are in reasonable agreement and they are summarized below. Belton and McCarron[1] have concluded that $WO_3·H_2O$ is the species responsible for the increased volatilization of W(cr) and WO_3(cr) in the presence of water vapor. Based on their data for W(cr) and the earlier data for WO_3(cr), Belton and McCarron[1] ruled out the possibility of significant amounts of $(WO_3)_2·H_2O$ and $WO_3·2H_2O$.

*Reactions: A) $W(cr) + 4H_2O(g) \rightarrow H_2WO_4(g) + 3H_2(g)$ B) $WO_3(cr) + H_2O(g) \rightarrow H_2WO_4(g)$

Heat Capacity and Entropy

The vibrational frequencies are estimated by comparison with those for H_2SO_4(g) reported by Giguere and Savoie,[6] and Chackalackal and Stafford.[7] These frequencies are also adjusted so that $S°(H_2WO_4, g, 1600\ K)$ is 136.7 $cal·K^{-1}·mol^{-1}$ as reported by Belton and McCarron.[1] This entropy was derived a 2nd law analysis of the equilibrium constants for reaction A.

The configuration of WO_4^- group is assumed to be tetrahedral. The bond angle W–O–H is estimated to be the same as the angle of H_2O(g). The bond distances are assumed to be the same as those in WO_3(g) and H_2O(g). The principal moments of inertia are: $I_A = 23.2705 \times 10^{-39}$, $I_B = 24.8660 \times 10^{-39}$, and $I_C = 24.9259 \times 10^{-39}$ $g·cm^2$.

Enthalpy of Formation

$\Delta_f H°$(298.15 K) was estimated by DiStefano *et al.*[1]. The $\Delta_f H°$(298.15 K) was estimated by taking 63% of the dissociation energy of PH_3 and using it as the dissociation energy of PH_2. Willes and Winkler[2] have estimated $\Delta_f H°(PH_2, g, 298.15\ K)$ to be 30 $kcal·mol^{-1}$.

Heat Capacity and Entropy

The vibratonal spectra of PH_2 from the flash photolysis of PH_3 has been reported by Ramsey[3] and in.[4] Similarities between the spectra of NH_2 and PH_2 were found. For NH_2 and NH_3 bond angles and bond distances were reported to be about the same. Byanalogy then the bond angles and bond distances of PH_2 and PH_3 should be nearly the same. The moments of inertia for PH_2 were therefore calculated from the molecular constants for PH_3. The principal moments of inertia are: $I_A = 0.2960 \times 10^{-39}$, $I_B = 0.3588 \times 10^{-39}$, and $I_C = 0.6548 \times 10^{-39}$ $g·cm^2$.

DiStefano *et al.*[1] have assumed the ground state degeneracy to be 2 because of the unpaired electron. The vibrational frequencies reported by DiStefano *et al.* have been used. They used a simple force field and the force constants of PH_3 to obtain the vibrational frequencies.

Enthalpy of Formation

The enthalpy of formation of $H_2S(g)$ determined by various workers including those reviewed in the previous JANAF analysis[1] were recalculated with the results shown below. No weight was given to the work performed prior to 1934 and less weight was given to the work of Kapustinskii and Kankovskii[7] because of the difficulty of establishing the state of the products.

Source	Reaction*	[from (1)]	$\Delta_f H°$(298.15 K), kcal·mol^{-1} Recalculated
Thomsen[2]	$H_2S(g) + HI_3(aq) = 3\ HI(aq) + S(amorph)$	–	−4.4, −5.1 if S(rhombic)
Thomsen[3]	$*H_2S(g) + O_2(g) = SO_2(g) + H_2SO_4·H_2O$	–	−2.0
Pollitzer[4]	$H_2S(g) + I_2(cr) = 2\ HI(g) + S(rh)$	–	−4.7, − 4.0 if S(amorph)
Lewis and Randall[5]	$3\ S(l) + 2\ H_2O(g) = SO_2(g) + 2\ H_2S(g)$	–	−3.6 ± 0.2
Zeumer and Roth[6]	$*H_2S(g) + O_2(g) = SO_2(g) + H_2SO_4·H_2O$	−4.80 ± 0.15	−4.89 ± 0.24
Kapustinskii and Kankovskii[7]	$*H_2S(g) + 3/2\ O_2(g) = SO_2(g) + H_2O(l) + S(rh)$	−4.9 ± 0.8	−4.92 ± 0.08

*Equations which are not balanced involve two reactions occurring in various proportions.

Heat Capacity and Entropy

The thermodynamic functions were taken from the JANAF table for $H_2S(g)$ dated (December 31, 1965).[1] These in turn were taken from Gordon[8] except below 298 K were they were calculated by the rigid–rotor, harmonic–oscillator approximation. Gordon had calculated $C_p°$ from 298 K to 6000 K by a method which takes into account second–order corrections for vibrational anharmonicity, vibration–rotation interaction, and centrifugal stretching. The spectroscopic constants used were taken from Allen and Plyler.[9]

The National Bureau of Standards prepared this table[10] by critical analysis of data existing in 1972. Using $\Delta_f H°$ selected by NBS,[10] we recalculate the table in terms of current JANAF reference states for the elements.

Enthalpy of Formation

The enthalpy of combustion of $TiH_{1.73}$(cr), the stable species of titanium hydride, was reported to be 247.8 $kcal·mol^{-1}$ by Sieverts and Gotta[1]. From this data the value of $\Delta_f H°(298.15\ K)$ for $TiH_{1.73}$(cr) was calculated to be 29.40 $kcal·mol^{-1}$. The enthalpy of dissociation of titanium hydride having compositions between the rough limits $TiH_{1.75}$ $TiH_{1.93}$ was given as 19.15 $kcal·mol^{-1}$ of H_2 dissociated by Gibb.[2] Assuming this value is applicable to compositions between the limits $TiH_{1.73}$ TiH_2, the difference in the enthalpy of formation of titanium hydride between $TiH_{1.73}$ and TiH_2 was estimated to be 5.17 $kcal·mol^{-1}$. Thus the value of $\Delta_f H°(298.15\ K)$ for TiH_2(cr) was calculated.

Heat Capacity and Entropy

The low temperature $C_p°$ for $TiH_{1.97}$(cr) were measured by Stalinski and Bieganski[3] 24 363 K). This data were adopted for TiH_2(cr) due to lack of the measured $C_p°$ values. A small but well marked type anomaly with a maximal value of $C_p°$ at 288.5 K in the $C_p°$ vs T curve was observed. $S°(298.15\ K)$ was reported by Stalinski and Bieganski[3] based on $S°(\text{extrap } 25\ K) = 0.65\ cal·K^{-1}·mol^{-1}$.

Enthalpy of Formation

$\Delta_f H$ (298.15 K) is estimated by linear interpolation between the values[1] of SiI_4(g) and SiH_4(g). There are no experimental $\Delta_f H°$ data for SiH_3I, SiH_2I_2 and $SiHI_3$. It is difficult to justify a nonlinear interpolation scheme such as that adopted for the chlorosilanes.[1] A cubic interpolation fits $\Delta_f H°$ data for the chloromethanes and has been proposed for bromomethanes and iodomethanes.[2] Experimental $\Delta_f H°$ values do not seem to eixst for CI_4, CBr_4 and $CHBr_3$, while published values for CBr_4 and $CHBr_3$ are the subject of controversy (SiH_3Br, g).[1] Moreover, the cubic scheme proposed[2] for CH_nI_{4-n} is surprisingly different from those of the other halomethanes;[2] i.e., the first differences in $\Delta_f H°$ exhibit a minimum instead of a maximum. These uncertainties preclude use of the iodomethanes for predicting $\Delta_f H°$ of the iodosilanes. Hunt and Sirtl[3] also concluded that linear interpolation of $\Delta_f H°$ is all that is justified by available data.

Heat Capacity and Entropy

The molecular structure is based on microwave data of Kewley *et al.*[4] for isotopic forms of the four monohalosilanes. The authors concluded that the silyl group is effectively the same in all four halides. We adopt effective (r_o) structural parameters rather than substitutional (r_s) parameters. These are in reasonable agreement with previous structural determinations.[5] The principal moments of inertia are $I_A = 0.9972 \times 10^{-39}$ and $I_B = I_C = 26.1748 \times 10^{-39}\ g \cdot cm^2$.

Vibrational frequencies are from gas-phase infrared spectra.[6,7] Assignments are consistent with liquid-phase Raman spectra[8,9] which yield slightly lower values for most of the frequencies.

We neglect excited states and assume the electronic ground state to be $^1A_1$ by analogy with CH_3I[10]. Comparison of the halosilanes[11] and halomethanes[10, 11] suggests that the lowest excited state of SiH_3I is at ≥30000 cm^{-1}. Contributions from this state should be unimportant.

Enthalpy of Formation

2nd and 3rd law analyses of equilibrium data for the reaction $1/2N_2(g)+3/2H_2(g) = NH_3(g)$ cited in the previous JANAF evaluation[1] plus more recent work of Schulz and Schaefer[6] were made using the revised thermal functions for NH_3(g). All of the previously cited work in reaction calorimetry plus the early work of Berthelot[7,8] and Thomsen[9] were reevaluated. No significant differences in the 3rd law calculations of the equilibrium data or in the corrections to the flow calorimetry data of Haber and Tamaru[12] and Wittig and Schmatz[13] were found. Thus, the 0.1 kcal discrepancy between the results of the equilibrium and reaction calorimetry measurements remains unresolved. The previous JANAF selection[1] for $\Delta_f H°(298.15\ K)$ of NH_3(g) was adopted. A recent evaluation[14] which includes new indirect calorimetry (unpublished) further confirms this selection.

Heat Capacity and Entropy

The thermodynamic functions differ from those of the 1965 JANAF table[1] in being taken directly form the later and more complete work of Haar.[15] Haar treated in detail the contribution of the highly anharmonic out–of–plane vibrational mode, including its large coupling with rotation and its coupling with the other vibrational modes. Haar's values of $C_p°$ pass through a shallow maximum between 4000 and 5000 K; they were extrapolated from 5000 to 6000 K by assuming a constant value (19.300 cal·K^{-1}·mol^{-1}). A summary of Haar's estimated uncertainties and of the differences of the 1965 table from the present table (in cal·K^{-1}·mol^{-1}) is as follows:

	Uncertainities (Haar, 15)		1965 Table minus This Table	
T,K	$C_p°$	$S°$	$C_p°$	$S°$
1000	0.006	0.006	−0.034	−0.033
3000	0.10	0.06	+0.142	−0.122
5000	0.6	0.04	+1.775	+0.265

The National Bureau of Standards prepared this table[16] by critical analysis of data existing in 1972. Using the results of Haar[15] and $\Delta_f H°$ selected by NBS,[16] we recalculate the table in terms of R=1.987192 cal·K^{-1}·mol^{-1} [17] and current JANAF reference states for the elements.

Enthalpy of Formation

The proton affinity of water has been measured by the ion impact method as −169 kcal·mol^{-1} by Tal'rose and Frankevitch.[1] The selected enthalpy of formation of hydronium ion, $\Delta_f H°(H_3O^+, g, 0\ K)$ = 139.1 kcal·mol^{-1}, was derived from the $\Delta_r H°(0\ K)$ = −169 kcal·mol^{-1} for $H_2O(g) + H^+(g) \rightarrow H_3O^+(g)$, using the JANAF $\Delta_f H°(H_2O, g, 0\ K)$ = −57.1 and $\Delta_f H°(H^+, g, 0\ K)$ = 365.2 kcal·mol^{-1}.

The values of 195 and 207 kcal·mol^{-1} for the enthalpy of formation of $H_3O^+(g)$ have also been reported by Field and Franklin[2] and Bernecker and Long,[3] respectively. These two values were based on the electron impact studies which may involve unaccounted excitations and excess energy in the fragments. Other literature values have been reviewed by Bishop.[4]

Green and Sugden,[5] based on the studies of the positive ions in flames by mass spectrometry, prefer the value derived from the proton affinity of water obtained by Tal'rose and Frankevitch, rather than the electron impact data. From the approximate equilibrium constant calculations for the reaction $HCO^+(g) + H_2O(g) = H_3O^+(g) + CO(g)$, Clifton[6] has also found that the heat of formation of $H_3O^+(g)$ derived from the proton affinity of water, not from the electron impact data, leads to agreement with the experimental data given by Green and Sugden.

Heat Capacity and Entropy

Since the molecule $H_3O^+(g)$ has the same number of valence electrons as $NH_3(g)$, a pyramidal molecular configuration (C_{3v}) is assumed for $H_3O^+(g)$ in the tabulation. Clifton[7] has obtained a bond distance O–H of 0.95 Å from an application of covalent bond radii and the effect of electric charge, and a bond angle H–O–H of 109° by extrapolating a plot of bond length versus bond angle for $NH_3(g)$ and $PH_3(g)$ to 0.95 Å. Both values are adopted in the tabulation. The principal moments of inertia are: $I_A = I_B 0.2446 \times 10^{-39}$, $I_C = 0.4005 \times 10^{-39}\ g \cdot cm^2$. Bishop[4] has calculated theoretically the bond distance OH of 0.95 Å and the bond angle H–O–H of 114° 26' with a planar D_{3h} molecular configuration. The vibrational frequencies were calculated by the valence force method from the estimated stretching and bending force constants of Clifton.

Hydronium, Ion ($H_3O_1^+$) — $H_3O_1^+(g)$

$S°(298.15\ K) = 110.544 \pm 0.4\ J \cdot K^{-1} \cdot mol^{-1}$
$T_{fus} = 315.5 \pm 5\ K$

$\Delta_f H°(0\ K) = -1265.9 \pm 2.1\ kJ \cdot mol^{-1}$
$\Delta_f H°(298.15\ K) = -1284.4 \pm 2.1\ kJ \cdot mol^{-1}$
$\Delta_{fus} H° = 13.389 \pm 0.8\ kJ \cdot mol^{-1}$

Enthalpy of Formation

Recent calorimetric measurements[1,2,3] indicate the National Bureau of Standards' selected values quoted in reference[4] $\Delta_f H°(H_3PO_4, cr, 298.15\ K) = -305.7 \pm 0.3\ kcal \cdot mol^{-1}$, is probably in error. The value was taken from Holmes' work.[5] The data are summarized below, with heat values based on white phosphorus reference state.

Source	Method	n Moles of H_2O	$\Delta_f H°(H_3PO_4, aq, 298.15\ K)$ kcal·mol^{-1}	$\Delta_f H°(298.15\ K)$ kcal·mol^{-1}
Head[1]	a & b	40	-309.34 ± 0.38	-307.0 ± 0.4
Birley[2]	a	100	-309.8 ± 0.35	-307.18 ± 0.5
Irving[3]	a	0.6416	-305.9 ± 0.5	-307.36 ± 0.5
Holmes[5]	a & b	–	–	-307.4 ± 0.5*

a = solution calorimetry; b = combustion calorimetry
* see text

Head and Lewis[1] determined the enthalpy of combustion of phosphorus and enthalpy of hydrolysis of combustion products which led to $\Delta_f H°(H_3PO_4 \cdot 40\ H_2O, aq, 298.15\ K) = -309.34 \pm 0.38\ kcal \cdot mol^{-1}$. Birley and Skinner[2] measured the enthalpy of hydrolysis of PCl_5 and derived $\Delta_f H°(H_3PO_4 \cdot 100\ H_2O, aq, 298.15\ K) = -309.8 \pm 0.35\ kcal \cdot mol^{-1}$ based on $\Delta_f H°(PCl_5, cr, 298.15\ K) = -106.0\ kcal \cdot mol^{-1}$ obtained by direct chlorination of phosphorus.[4] Irving and McKerrell[3] measured the enthalpy of solution of P_4O_{10} from which they derived $\Delta_f H°(H_3PO_4 \cdot 0.6416\ H_2O, aq, 298.15\ K) = -305.9 \pm 0.5\ kcal \cdot mol^{-1}$. Using enthalpy of solution data for $H_3PO_4(cr) \rightarrow H_3PO_4(363\ H_2O, aq)$,[5] and enthalpy of dilution data for $H_3PO_4(363\ H_2O, aq) \rightarrow H_3PO_4(n\ H_2O, aq)$[6] we obtain enthalpy of formation of H_3PO_4(cr) listed in the last column of the table. (These values are based on white phosphorus as the reference state.) Holmes[5] determined $\Delta_f H°(H_3PO_4, cr, 298.15\ K) = -305.7 \pm 0.3\ kcal \cdot mol^{-1}$ based on his enthalpy of combustion of white phosphorus and related enthalpy of solution data which were combined to form a thermal cycle. Using the white phosphorus based $\Delta_f H°(P_4O_{10}, cr, 298.15\ K) = -719.4\ kcal \cdot mol^{-1}$[7] (instead of his value $-713.2\ kcal \cdot mol^{-1}$, we have recalculated his thermal cycle and find $\Delta_f H°(H_3PO_4, cr, 298.15\ K) = -307.4 \pm 0.5\ kcal \cdot mol^{-1}$ which is in good agreement with the recent calorimetric measurements.[1,2,3]

The value, $307.0 \pm 0.5\ kcal \cdot mol^{-1}$, is tentatively selected for the enthalpy of formation of H_3PO_4(cr), based on white phosphorus as reference state.

Heat Capacity and Entropy

Low temperature heat capacity from 10 to 300 K were measured by Egan and Wakefield.[8] Their smooth $C_p°$ are adopted to the tabulation. Heat capacities above 300 K are estimated graphically based on the measured $C_p°$ curve.

The entropy $S°(298.15\ K)$ is derived from heat capacity data, using $S°(10\ K) = 0.04\ cal\ K^{-1} \cdot mol^{-1}$.

Fusion Data

Egan and Wakefield[8] measured calorimetrically the heat of fusion $\Delta_{fus} H° = 3.1 \pm 0.2\ kcal \cdot mol^{-1}$, but failed to determine the exact melting point due to continuous fusion between 301 to 319 K in their measurements. They suggested the melting point 315.5 K which was found by Ross and Jones.[9]

Holmes[5] derived the enthalpy of fusion $\Delta_{fus} H°(298.15\ K) = 3.2 \pm 0.5\ kcal \cdot mol^{-1}$ from his enthalpy of solution data for crystalline and liquid H_3PO_4 in water and in aq. $HClO_4$ solution, which corresponds to $\Delta_{fus} H° = 3.36\ kcal \cdot mol^{-1}$. We adopt an intermediate value of $\Delta_{fus} H° = 3.2 \pm 0.2\ kcal \cdot mol^{-1}$.

$S°(298.15\ K) = [150.775]\ J·K^{-1}·mol^{-1}$
$T_{fus} = 315.5\ K$

$\Delta_f H°(298.15\ K) = [-1271.663]\ kJ·mol^{-1}$
$\Delta_{fus} H° = 13.389 \pm 0.8\ kJ·mol^{-1}$

Enthalpy of Formation

$\Delta_f H°$ (H_3PO_4, l, 298.15 K) is calculated from that of the crystal by adding $\Delta_{fus} H°$ and the difference in enthalpy, $H°(315.5\ K) - H°(298.15\ K)$, between the crystal and liquid.

Heat Capacity and Entropy

Heat capacities of the liquid are estimated by comparison with those of H_2SO_4(cr, l)[1] and H_3PO_4(cr) $S°(298.15\ K)$ is calculated in a manner similar to that used for the enthalpy of formation.

Fusion Data

Refer to the crystal table for details.[2]

Decomposition Data

The phosphoric acid tends to be dehydrated to pyro– and meta–phosphoric acids when it is heated.

Enthalpy of Formation

The enthalpy of formation was derived by Gunn and Green.[1] In order to obtain the $\Delta_f H°(298.15\ K)$ they measured the enthalpy of explosive decomposition of phosphine gas. There is a good deal of uncertainty about the enthalpy of formation of PH_3(g), for instance:

$\Delta_f H°(298.15\ K)$	Source
$+3.6\ kcal·mol^{-1}$	The enthalpy of reaction between gaseous PH_3 and saturated bromine water[2]
$+6.3\ kcal·mol^{-1}$	The enthalpy of combustion of PH_3(g) in O_2(g) to form H_3PO_4[3].
$-2.34\ kcal·mol^{-1}$	Equilibrium data of.[4] Their data showed a wide variation in $\Delta_f H°$, as much as 11 $kcal·mol^{-1}$.
$+1.6\ kcal·mol^{-1}$	U.S. Nat. Bur. Stand.[5]

The enthalpy of formation have been reviewed by Cottrell[6] and by Bichowsky and Rossini.[7]

The enthalpy of formation selected was, $+1.3 \pm 0.4\ kcal·mol^{-1}$, as reported by Gunn and Green.[1] The selected enthalpy of formation was based on white (α) phosphorus.

Heat Capacity and Entropy

The fundamental wave number and degeneracy assignments are from the infrared spectral data by McConaghie and Nielsen.[8] The molecular constants are those obtained from infrared data by Nielsen.[9] Nielsen[9] has reported the molecular constants after calculating the Coriolis coupling effect between the wave numbers 2 and 4, or (992 cm^{-1}) and (1122.4 cm^{-1}).

The principal moments of inertia are: $I_A = I_B = 0.6264 \times 10^{-39}\ g·cm^2$ and $I_C = 0.7201 \times 10^{-39}\ g·cm^2$.

$T_{fus} = 274.69\ K$

$\Delta_f H°(298.15\ K) = 50.626 \pm 0.4\ kJ \cdot mol^{-1}$
$\Delta_{fus} H° = 12.657\ kJ \cdot mol^{-1}$

Enthalpy of Formation

Hughes *et al.*[1] measured the enthalpies of combustion of hydrazine and hydrazine monohydrate. The data, adjusted as suggested by Cole and Gilbert[2] are summarized below. Enthalpies of solution determined by Bushnell *et al.* interrelate N_2H_4(l). An intermediate value was selected from the resulting enthalpies of formation.

Source	Reaction	$\Delta_r H°(298.15\ K)$ kcal·mol^{-1}	$\Delta_f H°(298.15\ K)$ kcal·mol^{-1}
Hughes[1]	$N_2H_4(l) + O_2(g) \rightarrow N_2(g) + 2H_2O(l)$	−148.68 ± 0.06	12.05
Hughes[1]	$N_2H_4 \cdot H_2O(l) + O_2(g) \rightarrow N_2(g) + 3H_2O(l)$	−147.00 ± 0.06	–
Bushnell[3]	$N_2H_4(l) + H_2O(l) \rightarrow N_2H_4 \cdot H_2O(l)$	−1.80	12.17*

*From combination of second and third reactions.

Heat Capacity and Entropy

Heat capacities (12–340 K) of hydrazine crystal and liquid were determined by Scott *et al.*[4] Values beyond the experimental range for the liquid were extrapolated linearly. The entropy was obtained from the enthalpy of melting and the smoothed heat capacities of the crystal using $S°(12) = 0.023\ cal \cdot K^{-1} \cdot mol^{-1}$.

Fusion Data

Taken from Scott *et al.*[4]

Vaporization Data

The normal boiling point and enthalpy of vaporization are those calculated for the ideal gas from these tables. The boiling point found for the real gas (387.3 K) by Hieber and Woerner is in good agreement. The selected enthalpy of vaporization, $\Delta H°(298.15\ K) = 10.69$ kcal·mol^{-1}, is based on the vapor pressure data of Scott *et al.*,[4] series III. Vapor pressure measurements of Hieber and Woerner[5] are in satisfactory agreement as shown below.

Source	T/K	$\Delta_{vap} H°(298.15\ K)$, kcal·mol^{-1} 2nd law	3rd law	Drift cal·K^{-1}·mol^{-1}
Scott, *et al.*[4]	273–343	10.683 ± 0.003	10.696	0.05 ± 0.01
Chang, Gockcen[6]	276–325	10.40 ± 0.03	10.68	0.91 ± 0.09
Hieber, Woerner[5]	293–387	10.82 ± 0.03	10.71	−0.33 ± 0.07

The 2nd law 3rd law consistency of Scott *et al.* reflects the use of these data in selection of the gas phase functions (refer to H_4N_2 gas).

Product of the Moments of Inertia: $I_A I_B I_C = 7.3095 \times 10^{-117}\ g^3·cm^6$

Enthalpy of Formation

This was obtained from the enthalpy of formation of the liquid and the selected enthalpy of vaporization, $\Delta_f H°(298.15\ K) = 10.69\ kcal·mol^{-1}$, derived from the vapor pressure data (Series III) of Scott *et al.*[1] Other vapor pressure data from Hieber and Woerner[2] and Chang and Gokcen[3] are in satisfactory agreement (refer to the N_2H_4 liquid table).

Heat Capacity and Entropy

Functions were calculated from the constants given above using the rigid rotator harmonic oscillator method. The entropy ws increased by R ln 2 because two rotameric forms are implied by use of the torsional frequency. Small but arbitrary adjustments were made in the assignment of the bending mode frequencies in order to reproduce the vapor pressure data of Scott *et al.*[1] as closely as possible. Calculated values of $S°(298.15\ K) = 57.03$ and $S°(340\ K) = 58.70\ cal·K^{-1}·mol^{-1}$ may be compared with 56.99 and 58.69, respectively, derived from the data of Scott *et al*. Internal rotation calculations would require a complex potential function in order to fit the data. The barrier to inversion ($990\ cm^{-1}$ ~2.8 $kcal·mol^{-1}$) is slightly less than the barrier to internal rotation at the trans position ($1110\ cm^{-1}$ ~3.2 $kcal·mol^{-1}$) according to analyses of the microwave data by Kasuya[4] and Kasuya and Kojima.[5]

From matrix isolation and gas phase infrared studies, Catalano *et al.*[6] have suggested possible uncertainties in the assignment of the bending mode frequencies in the region from 1630 to 740 cm^{-1}. The question hinges on the uncertain existence of a gas phase fundamental at about 1600 cm^{-1} as observed by Giguere and Liu.[7] No corresponding matrix band was found and the gas phase band appeared to be due to absorption on the cell windows. A vapor phase Raman frequency at 1564 cm^{-1} was observed, however, by Kotov and Tatevskii.[8] Catalano *et al.* suggest one assignment based on the uncertain fundamental and a tentative alternative assignment excluding it. The two assignments give entropies that are 0.26 $cal·K^{-1}·mol^{-1}$ lower and 0.12 higher than the 3rd law value. The lower calculated entropy is probably more reasonable, but the higher value could be more easily modified to agree with the 3rd law value. Thus the alternative assignment was adopted with ν_{11} arbitrarily increased from ~810 to 933 cm^{-1}.

The structural constants are based primarily on the electron diffraction study of Morino *et al.*[9] Related analyses of the infrared fine structure of the torsional frequency (377 cm^{-1}), Yamaguchi *et al.*[10] and of the microwave spectra, Kasuya and Kojima[5] are in close agreement. The microwave data give an H–N–H angle of 106° and a torsional angle of 90°2'. Principal moments of inertia of the adopted structure are: $I_A = 0.5741 \times 10^{-39}$, $I_B = 3.5633 \times 10^{-39}$, and $I_C = 3.5734 \times 10^{-39}\ g·cm^2$.

$S°(298.15\ K) = 211.510 \pm 0.21\ J \cdot K^{-1} \cdot mol^{-1}$
$T_{fus} = 281.63 \pm 0.05\ K$

$\Delta_f H°(0\ K) = -1126.433 \pm 0.8\ kJ \cdot mol^{-1}$
$\Delta_f H°(298.15\ K) = -1127.621 \pm 0.8\ kJ \cdot mol^{-1}$
$\Delta_{fus} H° = 19.464 \pm 0.042\ kJ \cdot mol^{-1}$

Enthalpy of Formation

The enthalpy of formation of the monohydrate of sulfuric acid is derived from the enthalpy of solution data of Giauque *et al.*[1] We calculate $\Delta_f H°(298.15\ K)$ using $\Delta_r H°(298.15\ K) = -6.645\ kcal \cdot mol^{-1}$ for the solution process $H_2SO_4(l) + H_2O(l) = H_2SO_4 \cdot H_2O(l)$ and auxiliary data for H_2SO_4[2] and H_2O.[3]

Heat Capacity and Entropy

The heat capacity has been measured experimentally[4] in the range 15–300 K and has been re–analyzed and summarized by Giauque *et al.*[1] Above 300 K, the heat capacity values are derived from a nomograph constructed by Kharbanda[5] based on experimental data (273–573 K). These temperature–dependent values are corrected to current atomic weights, converted from IPTS–48 to IPTS–68, and adjusted graphically in the region 290–390 K so as to provide smoothly varying heat capacity values. In the region above 390 K, a linear dependence is assumed (as suggested from a least squares fit of the nomograph data); this linear dependence is used to obtain heat capacity data by extrapolation to 1000 K.

The entropy of 298.15 K is calculated by the appropriate integration of the crystal and liquid heat capacity values, addition of the entropy of melting, and $S°(15\ K) = 0.190\ cal \cdot K^{-1} \cdot mol^{-1}$.

Fusion Data

The melting point and enthalpy of melting have been measured calorimetrically by Rubin and Giauque.[4] The values used by Giauque *et al.*[1] in their re–evaluation and correlation of aqueous sulfuric acid properties were slightly different from those reported by Rubin and Giauque[4] the changes were 0.01 K in the melting point and 6 cal $K^{-1} \cdot mol^{-1}$ in the enthalpy of melting. In addition, the value for T_{fus} is corrected from IPTS–48 to IPTS–68.

Enthalpy of Formation

The adopted $\Delta_f H°(SiH_4, g, 298.15\ K) = 8.2 \pm 0.5\ kcal·mol^{-1}$ is derived from the enthalpy of decomposition measurements by Gunn and Green.[1] We have taken the average of the three measurements, $\Delta E = -7.83\ kcal·mol^{-1}$, to obtain $\Delta H = -7.24\ kcal·mol^{-1}$ for the decomposition. Some question exists about the final state of the silicon; we choose to consider it as amorphous and apply a correction of 1 $kcal·mol^{-1}$ to convert to the crystalline state[2] (the authors chose to neglect this correction). The results of Gunn and Green[1] are in good agreement with the value of $\Delta_f H°(SiH_4, g, 298.15\ K) = 7.8 \pm 3.5\ kcal·mol^{-1}$ determined by Brimm and Humphreys[3] from high temperature (680°C) enthalpy of decomposition measurements. We question the earlier negative values for the enthalpy of formation of $SiH_4(g)$[4-6] which range from − 8.7 to $-14.8\ kcal·mol^{-1}$ and the later result of Feher, *et al.*[7], $-11.3\ kcal·mol^{-1}$, because of suspected uncertainty in the final states and/or corrections for the final states.

Heat Capacity and Entropy

The four fundamental vibrational frequencies and the Si–H bond distance are the result of gas–phase infrared and Raman spectral studies by Kattenberg and Oskam.[8] They are in excellent agreement with values selected from earlier work as given in the compilations of Janz and Mikawa[9] and Shimanouchi.[10] The heat capacity and entropy calculations are based on a tetrahedral structure. The $S°(298.15\ K) = 48.89 \pm 0.01\ cal·K^{-1}·mol^{-1}$ is in good agreement with another evaluation.[2]

The principal moments of inertia are $I_A = I_B = I_C = 0.9784 \times 10^{-39}\ g·cm^2$.

PREVIOUS: June 1976 (1 atm) CURRENT: June 1976 (1 bar)

$S°(298.15\ K) = 276.363 \pm 0.42\ J \cdot K^{-1} \cdot mol^{-1}$
$T_{fus} = 233.70 \pm 0.05\ K$

$\Delta_f H°(0\ K) = -1422.274 \pm 0.8\ kJ \cdot mol^{-1}$
$\Delta_f H°(298.15\ K) = -1427.100 \pm 0.8\ kJ \cdot mol^{-1}$
$\Delta_{fus} H° = 18.242 \pm 0.17\ kJ \cdot mol^{-1}$

Enthalpy of Formation

The enthalpy of formation of the dihydrate of sulfuric acid is derived from the enthalpy of solution data of Giauque *et al.*[1] We calculate $\Delta_f H°(298.15\ K)$ for the dihydrate using $\Delta_f H°(298.15\ K) = -9.907\ kcal \cdot mol^{-1}$ for the solution process $H_2SO_4(l) + 2\ H_2O(l) = H_2SO_4 \cdot 2H_2O(l)$ and auxiliary data for H_2SO_4[2] and H_2O.[3]

Heat Capacity and Entropy

The heat capacity has been measured experimentally[4] in the range 15–300 K and has been summarized by Giauque *et al.*[1] Above 300 K, the heat capacity values are derived from a nomograph constructed by Kharbanda[5] based on experimental data (273–573 K). These temperature–dependent values are corrected to current atomic weights, converted from IPTS–48 to IPTS–68, and adjusted graphically in the region 290–310 K so as to provide smoothly varying heat capacity values. In the region above 310 K, a linear dependence is assumed (as suggested from a least squares fit of the nomograph data); this linear dependence is used to obtain heat capacity data by extrapolation to 1000 K.

The entropy at 298.15 K is calculated by the appropriate integration of the crystal and liquid heat capacity values, addition of the entropy of melting, and $S°(15\ K) = 0.363\ cal \cdot K^{-1} \cdot mol^{-1}$.

Fusion Data

The melting point and enthalpy of melting have been measured calorimetrically by Rubin and Giauque.[4] The melting point adopted in this table differs from that reported by Rubin and Giauque[4] by 0.02 K. This is due to the re analysis of the data by Giauque *et al.*[1] and a conversion of the resulting T_{fus} value from IPTS–48 to IPTS–68.

$S°(298.15\ K) = 345.373 \pm 0.42\ J \cdot K^{-1} \cdot mol^{-1}$
$T_{fus} = 236.78 \pm 0.05\ K$

$\Delta_f H°(0\ K) = -1716.249 \pm 0.8\ kJ \cdot mol^{-1}$
$\Delta_f H°(298.15\ K) = -1720.402 \pm 0.8\ kJ \cdot mol^{-1}$
$\Delta_{fus} H° = 23.999 \pm 0.21\ kJ \cdot mol^{-1}$

Enthalpy of Formation

The enthalpy of formation of the trihydrate of sulfuric acid is derived from the enthalpy of solution data of Giauque *et al.*[1] We calculate $\Delta_f H°(298.15\ K)$ for the trihydrate using $\Delta_r H°(298.15\ K) = -11.693\ kcal \cdot mol^{-1}$ for the solution process $H_2SO_4(l) + 3\ H_2O(l) = H_2SO_4 \cdot 3H_2O(l)$ and auxiliary data for H_2SO_4[2] and H_2O.[3]

Heat Capacity and Entropy

The heat capacity has been measured experimentally[4,5] in the range 15–300 K and has been summarized by Giauque *et al.*[1] Above 300 K, the heat capacity values are derived from a nomograph constructed by Kharbanda[6] based on experimental data (273–573 K). These temperature–dependent values are corrected to current atomic weights and converted from IPTS 48 to IPTS 68. Of the five hydrates of sulfuric acid (mono–, di–, tri–, tetra–, and hemihexa–) only in the case of the trihydrate is there a serious discrepancy in the heat capacity values (at ambient temperature) between Giauque *et al.*[6] and Kharbanda.[7] Assuming that the data of Giauque *et al.*[1] are correct and that the linear dependence suggested by the nomograph of Kharbanda[6] is correct, we have shifted the data derived from the nomograph by 0.78 $cal \cdot K^{-1} \cdot mol^{-1}$ to obtain a smooth junction of the low temperature and high temperature heat capacity data. The data are extrapolated linearly to 1000 K.

The entropy at 298.15 K is calculated by the appropriate integration of the crystal and liquid heat capacity values, addition of the entropy of melting, and $S°(15\ K) = 0.398\ cal \cdot K^{-1} \cdot mol^{-1}$.

Fusion Data

The melting point and enthalpy of melting have been measured calorimetrically by Hornung and Giauque.[5] The melting point adopted in this table differs from that reported by Hornung and Giauque[5] by 0.02 K. This is due to the re analysis of the data by Giauque *et al.*[1] and a conversion of the resulting T_{fus} value from IPTS–48 to IPTS–68.

$S°(298.15\ K) = 414.529 \pm 0.42\ J \cdot K^{-1} \cdot mol^{-1}$
$T_{fus} = 244.90 \pm 0.05\ K$

$\Delta_f H°(0\ K) = -2007.121 \pm 0.8\ kJ \cdot mol^{-1}$
$\Delta_f H°(298.15\ K) = -2011.199 \pm 0.8\ kJ \cdot mol^{-1}$
$\Delta_{fus} H° = 30.644 \pm 0.25\ kJ \cdot mol^{-1}$

Enthalpy of Formation

The enthalpy of formation of the tetrahydrate of sulfuric acid is derived from the enthalpy of solution data of Giauque *et al.*[1] We calculate $\Delta_f H°(298.15\ K)$ for the tetrahydrate using $\Delta_r H°(298.15\ K) = -12.880\ kcal \cdot mol^{-1}$ for the solution process $H_2SO_4(l) + 4H_2O(l) = H_2SO_4 \cdot 4H_2O(l)$ and auxiliary data for H_2SO_4[2] and H_2O.[3]

Heat Capacity and Entropy

The heat capacity has been measured experimentally[4] in the range 15–300 K and has been summarized by Giauque *et al.*[1] Above 300 K, the heat capacity values are derived from a nomograph constructed by Kharbanda[5] based on experimental data (273–573 K). These temperature-dependent values are corrected to current atomic weights, converted from IPTS–48 to IPTS–68, and adjusted graphically in the region 300–330 K so as to provide smoothly varying heat capacity values. In the region above 350 K, a linear dependence is assumed (as suggested from a least squares fit of the nomograph data); this linear dependence is used to obtain heat capacity data by extrapolation to 1000 K.

The entropy at 298.15 K is calculated by the appropriate integration of the crystal and liquid heat capacity values, addition of the entropy of melting, and $S°(15\ K) = 0.687\ cal \cdot K^{-1} \cdot mol^{-1}$.

Fusion Data

The melting point and enthalpy of melting have been measured calorimetrically by Hornung and Giauque.[4] The values adopted in this table for T_{fus} and $\Delta_{fus}H°$ differ from those reported by Hornung and Giauque[4] by 0.02 K and 2 $cal \cdot mol^{-1}$, respectively. This is due to the re-analysis of this data by Giauque *et al.*[1] and a conversion of the resulting T_{fus} value from IPTS–48 to IPTS–68.

$S°(298.15\ K) = 587.819 \pm 0.63\ J \cdot K^{-1} \cdot mol^{-1}$
$T_{fus} = 220.30 \pm 0.05\ K$

$\Delta_f H°(0\ K) = -2727.58 \pm 0.8\ kJ \cdot mol^{-1}$
$\Delta_f H°(298.15\ K) = -2733.26 \pm 0.8\ kJ \cdot mol^{-1}$
$\Delta_{fus} H° = 34.116 \pm 0.25\ kJ \cdot mol^{-1}$

Enthalpy of Formation

The enthalpy of formation of the hemihexahydrate of sulfuric acid is derived from the enthalpy of solution data of Giauque *et al.*[1] We calculate $\Delta_f H°(298.15\ K)$ for the hemihexahydrate using $\Delta_r H°(298.15\ K) = -14.669\ kcal \cdot mol^{-1}$ for the solution process $H_2SO_4(l) + 6.5H_2O(l) = H_2SO_4 \cdot 6.5H_2O(l)$ and auxiliary data for H_2SO_4[2] and H_2O.[3]

Heat Capacity and Entropy

The heat capacity has been measured experimentally[4] in the range 15–300 K and has been summarized by Giauque *et al.*[1] Above 300 K, the heat capacity values are derived from a nomograph constructed by Kharbanda[5] based on experimental data (273–573 K). These temperature dependent values are corrected to current atomic weights, converted from IPTS 48 to IPTS 68, and adjusted graphically in the region 300–320 K so as to provide smoothly varying heat capacity values. In the region above 350 K, a linear dependence is assumed (as suggested from a least squares fit of the nomograph data); this linear dependence is used to obtain heat capacity data by extrapolation to 1000 K.

The entropy at 298.15 K is calculated by the appropriate integration of the crystal and liquid heat capacity values, addition of the entropy of melting, and $S°(15\ K) = 0.721\ cal \cdot K^{-1}\ mol^{-1}$.

Fusion Data

The melting point and enthalpy of melting have been measured calorimetrically by Hornung *et al.* These data were reevaluated by Giauque *et al.*[1] We have adopted the revised values and have also corrected T_{fus} to the IPTS–68.

Heat of Formation

Zero by definition.

Heat Capacity and Entropy

Information on the electronic energy levels and quantum weights is taken from Moore[1] and Martin.[9] All predicted levels have been observed through n=4 but above that many predicted levels are missing. Our calculations indicate that any reasonable method of filling in these missing levels and cutting off the summation in the partition function[2] has no effect on the thermodynamic properties to 6000 K. This is undoubtedly a result of the high energy of these levels; the first excited level is over 159000 cm^{-1} above the ground state. Therefore, we list the ground state only. Extension to higher temperatures may require consideration of excited states and utilization of different fill and cutoff procedures.[2]

The thermodynamic functions at 298.15 K agree exactly with recent CODATA recommendations[3] except for two minor differences. First, the entropy differs by 0.1094 $J·K^{-1}·mol^{-1}$ because this table uses a standard-state pressure of 1 bar, whereas the CODATA recommendations are based on 1 atm. Second, entropy differences of the order of 0.001–0.004 $J·K^{-1}·mol^{-1}$ for the rare gases arise due to the use of slightly different values for R; this table uses R = 8.31441 $J·K^{-1}·mol^{-1}$. Considering these minor changes, this table agrees within the estimated uncertainty with those by Hultgren *et al.*,[4] McBride *et al.*,[5] Gurvich *et al.*,[8] and Wagman *et al.*[12] The estimated uncertainty is due to uncertainties in the relative atomic mass and fundamental constants, which are based on the 1981 scale[6] and the 1973 values,[7] respectively.

The thermodynamic functions reported here are calculated assuming that helium gas obeys Boltzmann statistics. In fact helium is a Bose–Einstein gas.[4] However, the differences in thermal properties between the two are very small except at extremely low temperature.[10,11] At 298.15 K the difference in $C_p°$ amounts to only 0.004 $J·K^{-1}·mol^{-1}$ and will be less at higher temperatures. Since $C_p°$ is the most sensitive of the thermodynamic properties, the differences are well within the stated uncertainty. At temperatures below approximately 50 K the differences may become significant and Bose–Einstein statistics should be used.

Phase Data

The boiling point, 4.215 K (1 atm), is taken from Hultgren *et al.* This value should prove reasonably accurate, although it has not been evaluated by the present authors, and is furnished for the convenience of the reader. As a result of this low value, the reference state for helium is chosen to be the ideal gas at all temperatures. This may differ from the choice of other authors.

Heat of Formation

The ionization limit of neutral helium (198310.76 ± 0.02 cm^{-1}) reported by Moore[1] and Martin,[10] is adopted as $\Delta_f H°$(0 K) for He^+(g). The ionization limit is converted from cm^{-1} to $kJ·mol^{-1}$ using the factor, 1 cm^{-1} = 0.01196266 $kJ·mol^{-1}$, which is derived from the latest CODATA fundamental constants.[2] The uncertainty in the ionization limit corresponds to an uncertainty of less than 0.001 $kJ·mol^{-1}$ in the heat of formation. Rosenstock *et al.*[9] have summarized additional ionization potential and appearance potential data. Gurvich *et al.*[8] and Wagman *et al.*[11] adopted the same ionization potential, but the use of slightly different fundamental constants by Wagman *et al.*[11] resulted in a heat of formation difference of 0.021 $kJ·mol^{-1}$.

$\Delta_f H°$(He^+, g, 298.15 K) is obtained from $\Delta_f H°$(He, g, 0 K) by using IP(He) with JANAF[3] enthalpies $H°$(0 K)–$H°$(298.15 K) for He^+(g), He(r), and e^-(r). $\Delta_r H°$(He → $He^+ + e^-$, 298.15 K) differs from a room temperature threshold energy due to inclusion of these enthalpies and to threshold effects discussed by Rosenstock *et al.*[9] $\Delta_f H°$(298.15 K) should be changed by −6.197 $kJ·mol^{-1}$ if it is to be used in the ion convention that excludes the enthalpy of the electron.

Heat Capacity and Entropy

The information on electronic energy levels and quantum weights given by Moore[4] is complete to n=14. Our calculations indicate that any reasonable method of including these levels and cutting off the summation in the partition function[5] has no effect on the thermodynamic functions to 6000 K. This is a result of the high energy of these levels; the first excited level is over 329000 cm^{-1} above the ground state. Since inclusion of these upper levels has no effect on the thermodynamic functions (to 6000 K) we list only the ground state. The reported uncertainty in $S°$(298.15 K) is due to uncertainties in the relative ionic mass and fundamental constants. Extension of these calculations above 6000 K may require consideration of the higher excited states and use of different fill and cutoff procedures.[5]

The thermodynamic functions reported here agree with those of Green *et al.*,[6] Hilsenrath *et al.*,[7] and Gurvich *et al.*[8] except for one or two minor differences. First, the entropy differs by 0.1094 $J·K^{-1}·mol^{-1}$ because this table uses a standard-state pressure of 1 bar, whereas the cited references used a pressure of 1 atm. Second, smaller differences arise from the use of slightly different values for the fundamental constants and the relative ionic mass.

$S°(298.15\ K) = 43.560\ J·K^{-1}·mol^{-1}$
$T_{trs} = 2054 \pm 50\ K\ (\alpha–\beta)\ K$

$\Delta_f H°(0\ K) = 0\ kJ·mol^{-1}$
$\Delta_f H°(298.15\ K) = 0\ kJ·mol^{-1}$
$\Delta_{trs} H° = 5.908 \pm 0.2\ kJ·mol^{-1}$

Enthalpy of Formation

Zero by definition.

Heat Capacity and Entropy

The adopted thermal functions for α–Hf(cr) are derived from the studies of Collings and Ho,[1] Westrum,[2] Hawkins *et al.*[3] and Cezairliyan and McClure.[4] The mathematical and graphical treatment of these four studies yields a continuous and smooth heat capacity curve.

Roberts[5] surveyed the superconductive properties of the elements and reported a critical temperature of 0.128 K for α–Hf(cr). Since this temperature is so low, the effects of superconductivity on the thermal functions are not considered.

There are four studies[1,6–8] on the heat capaicty of hafnium in the region 1–5 K. Only Wolcott[6] reported the experimental data (56 data points). In the other three states, an equation (with two constants) was given to describe the entire set of experimental data. The second set of constants given by Betterton and Scarbrough[8] are stated to be an average of the two studies of Kneip *et al.*[7] and the more recent study by Betterton and Scarbrough.[8] However, the values appear suspect and may contain a typographical error. Nevertheless the maximum difference in the calculated values for $S°(5\ K)$ is $0.00024\ cal·K^{-1}·mol^{-1}$ with the adopted value being $S°(5\ K) = 0.0038\ cal·K^{-1}·mol^{-1}$. Similarily for $C_p°(5\ K)$ the maximum difference is $0.00024\ cal·K^{-1}·mol^{-1}$, with the adopted value being $C_p°(5\ K) = 0.00638\ cal·K^{-1}·mol^{-1}$

In the region above 5 K, and below 350 K, there are four heat capacity studied.[2,9–11] Cristescu and Simon[9] studies Hf from 13 to 210 K and reported 15 heat capacity values with a peak near 75 K. Burk and Darnell[10] made heat capacity measurements (40–190 K) and reported that the peak is completely absent. The heat capacity measurements of Burk *et al.* (10–200 K),[11] and Westrum (5.82–348.55 K)[1,12] support this latter conclusion, i.e., no peak. The values of Burk *et al.*,[11] after correction for the ~2% Zr in this sample, agree with the data of Westrum[2,12] between 10 and 40 K but deviate above 40 K, becoming ~5% higher at 100 K and decreasing to ~1% higher at 200 K. Above 350 K, there are four heat capacity studies and four enthalpy studies:

	Source (Year)	Data Points	T/K	Wt % Zr in Hf Sample

	Golutvin and Maslennikova (1970)[15]	9	695–137	0.79
Heat Capacity	Peletskii *et al.* (1971)[16]	13 (smoothed)	1200–2200	0.66
	Arutyunov *et al.* (1972)[17]	16 (smoothed)	1100–2050	0.65
	Cezairliyand and McClure (1975)[4]	26	1500–2400	3.12
	Rumyantsev *et al.* (1979)[18]	graph	1000–1900	–

The enthalpy studies show an unusually large scatter within each study as well as a lack of agreement between the studies. The heat capacity studies all have a similar temperature dependence in comparison with the adopted values. However, the studies of Arutyunov *et al.*[17,19] and Rumyantsev *et al.*[18] lie roughly 10% higher than the adopted values, whereas the study of Peletskii *et al.*[16] lies 5–24% below. The studies by Arutyunov *et al.*[17,19] and Rumyantsev *et al.*[18] suggest a sharp decrease in the heat capacity values within 50 K of the α–β transition temperature. The experimental results were corrected for this zirconium content.

Transition Data

Refer to the β–crystal table for details.

Sublimation Data

There are no sublimation studies involving α–Hf(cr). The enthalpy of sublimation is calculated as the difference between the enthalpy of formation of the ideal gas and the enthalpy of formation of α–Hf(cr).

PREVIOUS: CURRENT: March 1979

$S°(298.15\ K) = [61.104]\ J·K^{-1}·mol^{-1}$
$T_{trs} = 2054 \pm 50\ K\ (\alpha–\beta)\ J·K^{-1}$
$T_{fus} = 2500 \pm 20\ K\ (\beta–l)\ J·K^{-1}$

$\Delta_f H°(298.15\ K) = [18.686]\ kJ·mol^{-1}$
$\Delta_{trs}H° = 5.908 \pm 0.2\ kJ·mol^{-1}$
$\Delta_{fus}H° = [29.288 \pm 4.2]\ kJ·mol^{-1}$

Enthalpy of Formation

The enthalpy of formation is calculated from that of the α–crystal by addition of $\Delta_{trs}H°$ and the difference in enthalpy, $H°(2054\ K)–H°(298.15\ K)$, between the α–crsytal and β–crystal.

Heat Capacity and Entropy

The only heat capacity study for the β–crystal is that of Cezairliyand McClure.[1] Using a pulse heating technique, they studied the heat capacity of a sample containing 3.12% (wt) Zr in the range 2054 to 2400 K. These results were corrected by Cezairliyan and McClure[1] to represent pure β–Hf and are extrapolated linearly to the melting point, 2500 K, and to 298.15 K. The entropy at 298.15 is calculated in a manner similar to that for the enthalpy of formation.

Phase Data

Hafnium, at ambient pressures, exists in two crystal modifications. The low temperature form, α–Hf, is hexagonal close packed, an hcp(A3) structure isotypic with Mg. The high temperature form, β–Hf, is body centered cubic, a bcc(A2) structure isotypic with W. The wide variation in the observed transition temperature is undoubtedly due to the effects of various impurities, in particular, zirconium.

Transition Data

Cezairlivan and McClure[2] have summarized the reported transition temperatures for the α to β transition of hafnium. Their summary is given below. All temperatures were corrected to IPTS–68. The pure hafnium value reported by the cited author was corrected for the zirconium content of the alloy. Hultgren *et al.*,[18] based on data available through 1965, recommended $T_{trs} = 2013 \pm 20$ K. We adopt $T_{trs} = 2054 \pm 50$ K based on the study of Cezairliyan and McClure[2] since we have also adopted their measured heat capacity values. In addition there are many studies of binary phase diagrams which lend support to this adopted value.

Cezairliyan and McClure (1976)[2]	3.12	2012 ± 10	2054

Cezairliyand and McClure,[2] using a millisecond–resolution pulse–heating technique, measured the transformation enthalpy to be 33.1 $J·g^{-1}$ (1.412 ± 0.05 $kcal·mol^{-1}$). Peletskii and Druzhinin[14] measured 29 J g^{-1} (1.237 $kcal·mol^{-1}$), a value which is roughly 12% lower than that of Cezairliyan and McClure.[2] Martynyuk and Tsapkov,[16] using a continuous–pulse heating technique, measured a transformation enthalpy of 1.24 $kcal·mol^{-1}$. The samples used in all three studies contained significant amounts of zirconium wt %,[2] 0.66 wt %,[14] and 0.7 wt %,[16] respectively. Hoerster *et al.*[17] measured an enthalpy of transition of 0.52 $kcal·mol^{-1}$ at 2090 K. We adopted $\Delta_{trs}H° = 1.412 \pm 0.05\ kcal·mol^{-1}$ as derived from the study of Cezairliyan and McClure.[2]

Fusion Data

Refer to the liquid table.

Sublimation Data

The sublimation studies for β–Hf(cr) are summarized on the Hf(g) table. The enthalpy of sublimation for Hf(β,cr) is calculated as the difference in the enthalpies of formation at 298.15 K of Hf(g) and Hf(β,cr).

PREVIOUS: CURRENT: March 1979

$S°(298.15\ K) = [71.938]\ J·K^{-1}·mol^{-1}$
$T_{fus} = 2500 \pm 20\ K$

$\Delta_f H°(298.15\ K) = [46.209]\ kJ·mol^{-1}$
$\Delta_{fus}H° = [29.288 \pm 4.2]\ kJ·mol^{-1}$

Enthalpy of Formation

The enthalpy of formation is calculated from that of the β–crystal by addition of $\Delta_{fus}H°$ and the difference in enthalpy, $H°(2500\ K)–H°(298.15\ K)$, between the β–crystal and liquid.

Heat Capacity and Entropy

There are no heat capacity or enthalpy studies covering the liquid region of hafnium. A constant value of $C_p° = 9.0\ cal·K^{-1}·mol^{-1}$ is assumed for the region 1820–5500 K. A glass transition is assumed at 1820 K below which extrapolated β–Hf heat capacity values are used. The entropy is calculated in a manner similar to that used for the enthalpy of formation.

Fusion Data

Garg and Ackermann,[1] using pyrometric techniques, measured the melting point of hafnium as 2501 ± 3 K. Hultgren *et al.*[2] reviewed nine studies available through 1955 and recommended $T_{fus} = 2500 \pm 20$ K. We adopted $T_{fus} = 2500 \pm 20$ K.

The studies (and the reported melting temperatures in K) examined by Hultgren *et al.*[2] are: DeBoer and Fast,[3] 2503 ± 50; Skinner *et al.*,[4] 2498; Litton,[5] 2403; Adenstedt,[6] 2248; Spedding,[7] 2508 ± 5; Deardoff and Hayes,[8] (2495 ± 20; Gregorovitch,[9] 2116; Taylor *et al.*,[10] 2503 ± 20.

Ackermann and Rauh[11] measured a melting point of 2467 ± 4 K in a HfO_2 container. However, they state that the melting point may be as high as 2495 K since their sample contained 0.7 wt % Zr.

The enthalpy melting for Hf has not been measured. Various estimates and calculations have been made. Martynyuk *et al.*[12] correlated graphically $\Delta_{fus}S°$ versus T_{fus} for many metals and used the resulting linear relationship to estimate $\Delta_{fus}H° = 7.0\ kcal·mol^{-1}$. We adopt this value. Ackermann and Rauh[13] measured vapor pressures over Hf(β,cr) and Hf(l), adjusted the vapor pressures for Hf(β,cr) to match those of Hf(l) at T_{fus}, and derived $\Delta_{fus}H° = 6.2\ kcal·mol^{-1}$.

Vaporization Data

The vaporization studies are summarized on the ideal gas table.

The boiling point is calculated as that temperature for which $\Delta G° = 0$ for Hf(l)=Hf(g). $\Delta_{vap}H°$ is the corresponding enthalpy change. T_{vap} is the temperature at which the fugacity is one bar. The normal boiling point (p=1 bar) would be a slightly lower temperature.

Enthalpy of Formation

There are six sublimation studies and two vaporization studies from which an enthalpy of formation for Hf(g) could be derived. A plot of these vapor pressure data, log p vs $1/T$, reveals considerable discrepancy between the various studies. In the liquid region, the vapor pressure values of Koch *et al.*[1] and Ackermann and Rauh[2] are in close agreement. The pressures of the former study are 5% higher at 2500 K but become 10% lower at 2800 K. The measured temperatures in the former study[1] were adjusted (i.e., the pyrometer reading) by Koch *et al.*[1] so that at the observed melting point the temperature would be 2500 K. The sample purity was not stated. In the latter study[2] the reported vapor pressures were corrected pressures (assuming ideal solution) from a eutectic of Hf and W. The Hf sample had a measured melting point of 2464 K; the purity was not reported.

The sublimation studies of Golubtsov and Mikul'skaya[3] and Ackermann and Rauh[2] spanned a temperature range which involved the α- and β-phases of hafnium, yet neither study mentioned the characterization of the condensed phase. The study of Golubtsov and Mikul'skaya[3] is not considered further since their reported vapor pressure equation is ambiguous and cannot be easily modified to yield reasonable vapor pressures. In general terms, the sublimation pressures of Ackermann and Rauh,[2] Kibler *et al.*[4] and McClaine and Blackburn[5] are in reasonable agreement. The pressures of Panish and Reif[6] are 60% above these three studies;[2,4,5] there is considerable scatter with one distinctly low pressure point at 2113 K. On the other hand, the results of Trulson *et al.*[7] are substantially lower by 50% than the three studies[2,4,5] with two distinctly lower points.

A 2nd and 3rd law analysis is given in the following table. We adopt $\Delta_f H°$ (Hf, g, 298.15 K) = 147.8 ± 1.5 $kcal·mol^{-1}$. This result is based on the reasonable consistency of the two vapor pressure studies[2,4] with each other and with our adopted thermodynamic functions as evidenced by the small values of the drift. Hultgren *et al.*,[8] using different thermodynamic functions and data available through 1966, recommended an enthalpy of formation of 148.0 ± 1.0 $kcal·mol^{-1}$ based heavily on the study by Kibler *et al.*[4] Other values for $\Delta_f H°(298.15\ K)$, also derived from vapor pressure studies, have been reported by Krupka,[9] Krikorian[10] and Kibler *et al.*[11]

*Reaction: A) Hf(β,cr) = Hf(g) B) Hf(l) = Hf(g)
[b]Two points discarded due to a statistical test.

Heat Capacity and Entropy

The electronic energy levels are given in the compilation by Meggers and Moore.[12] Although we have listed only the ground state, the lowest two excited states, the highest observed excited state (below the ionization potential), and the ionization potential for Hf(g), all levels listed by Meggers and Moore,[12] as well as estimated levels (for n = 5,6,7), are used in the calculation. The 233 observed levels, two of which lie above the ionization potential, are too numerous to list completely. In our calculations, the missing levels for n = 6 and 7 have been arbitrarily added near the ionization limit. The calculations indicate that for Hf(g) the thermodynamic functions up to at least 3000 K are independent of the estimated missing levels (for n = 6 and 7), the cut–off procedure, and the inclusion of n = 7 levels. At this temperature there are no experimental heat capacity enthalpy, or vapor pressure data. The Gibbs energy function is essentially unaffected up to 5500 K.

Enthalpy of Formation

$\Delta_f H°(Hf^+, g\ 0\ K)$ is calculated from $\Delta_f H°(Hf, g, 0\ K)$[1] using the spectroscopic value of $IP(Hf) = 54700 \pm 600\ cm^{-1}$ ($654.358 \pm 1.18\ kJ·mol^{-1}$) from Meggers and Moore.[2] The ionization limit is converted from cm^{-1} to $kJ·mol^{-1}$ using the factor, $1\ cm^{-1} = 0.01196266\ kJ·cm^{-1}$, which is derived from the 1973 CODATA fundamental constants.[3] Rosenstock *et al.*[4] and Levin and Lias[5] have summarized additional ionization and appearance potential data.

$\Delta_f H°(Hf^+, g, 298.15\ K)$ is calculated from $\Delta_f H°(Hf, g, 0\ K)$ by using IP (Hf) with JANAF[1] enthalpies, $H°(0\ K)–H°(298.15\ K)$, for Hf(g), $Hf^+(g)$, and $e^-(g)$. $\Delta_f H°(Hf \rightarrow Hf^+ + e^-, 298.15\ K)$ differs from a room temperature threshold energy due to inclusion of these enthalpies and to threshold effects discussed by Rosenstock *et al.*[4] $\Delta_f H°(298.15\ K)$ should be changed by $-6.197\ kJ·mol^{-1}$ if it is to be used in the ion convention that excludes the enthalpy of the electron.

Heat Capacity and Entropy

The electronic energy levels are given in the compilation by Moore.[6] Although we have listed only the ground state, the first excited state, the highest observed excited state, and the ionization potential for $Hf^+(g)$, all levels listed by Moore,[6] as well as estimated levels (for $n = 6$ and 7), are used in the calculation. The 121 observed levels are too numerous to list completely. In our calculations the missing levels for $n = 6$ and 7 have been arbitrarily added near the ionization limit. The calculations indicate that for $Hf^+(g)$ the thermodyanmic functions up to 5000 K are independent of the estimated missing levels (for $n = 6$ and 7), the cut–off procedure, and the inclusion of n=7 levels. The free energy function is unaffected up to 10000 K. The reported uncertainty in $S°_{298}$ is due to uncertainties in the gram formula weight and the fundamental constants. Extension of these calculations above 6000 K may require consideration of the higher excited states (n>7), more precise estimation of the missing levels (for all n), and utilization of proper fill and cut–off procedures.[7]

EA(Hf, g) = 0.0 eV
$S°(298.15\ K) = 185.040 \pm 0.002\ J \cdot K^{-1} \cdot mol^{-1}$

$\Delta_f H°(0\ K) = 618.040 \pm 6.3\ kJ \cdot mol^{-1}$
$\Delta_f H°(298.15\ K) = [612.197]\ kJ \cdot mol^{-1}$

Electonic Level and Quantum Weight		
State	ϵ_i, cm^{-1}	g_i
$^4F_{3/2}$	0.0	4

Enthalpy of Formation

$\Delta_f H°(Hf^-, g, 0\ K)$ is calculated from $\Delta_f H°(Hf, g, 0\ K)$[1] using the adopted electron affinity of EA(Hf) = ~0.0 eV. This value, recommended by Hotop and Lineberger,[2] is based on a semiempirical extrapolation.[3,4] Additional information on Hf^-(g) and may be obtained in the critical discussions of Hotop and Lineberger,[2,4] Rosenstock *et al.*[5] and Massey.[6]

$\Delta_f H°(Hf^-, g, 298.15\ K)$ is obtained from $\Delta_f H°(Hf, g, 0\ K)$ by using EA(Hf) with JANAF[1] enthalpies, $H°(0\ K)$–$H°(298.15\ K)$, for Hf^-(g), Hf(g), and e^-(ref). $\Delta_f H°(Hf^- \rightarrow Hf + e^-, 298.15\ K)$ differs from a room-temperature threshold energy due to inclusion of these enthalpies and to threshold effects discussed by Rosenstock *et al.*[5] $\Delta_f H°(298.15\ K)$ should be changed by +6.197 $kJ \cdot mol^{-1}$ if it is to be used in the ion convention that excludes the enthalpy of the electron.

Heat Capacity and Entropy

The ground state electronic configuration for Hf^-(g) is given by Hotop and Lineberger[2,4] and Rosenstock *et al.*[5] Lacking any experimental evidence as to the stability of any excited states, we assume that no stable excited states exist.

$S°(298.15\ K) = 76.03 \pm 0.2\ J·K^{-1}·mol^{-1}$
$T_{fus} = 234.29\ K$

$\Delta_f H°(0\ K) = 0\ kJ·mol^{-1}$
$\Delta_f H°(298.15\ K) = 0\ kJ·mol^{-1}$
$\Delta_{fus} H° = 2.2953 \pm 0.0004\ kJ·mol^{-1}$

Enthalpy of Formation

Zero by definition.

Heat Capacity and Entropy

The heat capacities of Smith and Wolcott, (1.2-20.2 K),[1] Busey and Giaugue (15-330 K),[2] and Douglas *et al.* (300-770 K),[3] have been smoothly joined. There is fair agreement between the selected values and those of Pickard and Simon,[4] Carpenter and Oakley,[5] Carpenter and Stoodley,[6] Cohen *et al.*,[7] Dixon and Rodebush,[8] Simon,[9] Bronsted,[10] and Pollitzer.[11]

Fusion Data

The results of Busey and Giauque[2] are adopted.

Vaporization Data

Refer to the gas phase tables for details.

Enthalpy of Formation

The value adopted for the enthalpy of formation of Hg(g) is that recommended by CODATA.[1] This value was derived from the vapor pressure studies summarized by Hultgren *et al.*[2] Of the 24 studies examined, most weight was given to the following studies: Spedding and Dye (533–630 K),[3] Menzies (395 625 K),[4] Beattie *et al.* (623–635 K),[5] Burlingame (343–474 K),[6] Rodebush and Dixon (444–476 K),[7] and Mayer (262–298 K).[8]

Heat Capacity and Entropy

The information on electronic energy levels and quantum weights, given by Moore,[9,10] is incomplete because many theoretically predicted levels have not been observed. Our calculations indicate that any reasonable method of filling in these missing levels and cutting off the summation in the partition function[11] has no effect on the thermodynamic functions to 6000 K. This is a result of the high energy of all levels other than the ground state and the three levels below 45000 cm^{-1}; the next excited state is approximately 54000 cm^{-1} above the ground state. Since inclusion of these excited states has no effect on the thermodynamic functions (to 6000 K), we list only the ground state and the three P levels. The reported uncertainty in $S°$(298.15 K) is due to uncertainties in the relative ionic mass and the fundamental constants. Extension of these calculations above 6000 K may require consideration of the excited states and use of different fill and cutoff procedures.[11]

The thermal functions at 298.15 K agree with the CODATA recommendations[1] except that the entropy differs by 0.1094 $J·K^{-1}·mol^{-1}$, since this table uses a standard state pressure of 1 bar (CODATA recommendations are based on 1 atm).

Enthalpy of Formation

$\Delta_f H°(Hg^+, g, 0\ K)$ is calculated from $\Delta_f H°(Hg, g, 0\ K)$[1] using the spectroscopic value of IP(Hg) = 84184.1 ± 0.5 cm^{-1}(1007.066 ± 0.006 $kJ·mol^{-1}$) from Moore.[2] The ionization limit is converted from cm^{-1} to $kJ·mol^{-1}$ using the factor, 1 cm^{-1} = 0.01196266 $kJ·mol^{-1}$, which is derived from the 1973 CODATA fundamental constants.[3] Rosenstock *et al.*[4] and Levin and Lias[5] have summarized additional ionization and appearance potential data.

$\Delta_f H°(Hg^+, g, 298.15\ K)$ is calculated from $\Delta_f H°(Hg, g, 0\ K)$ by using IP(Hg) with JANAF[1] enthalpies, $H°(0\ K)-H°(298.15\ K)$, for Hg(g), $Hg^+(g)$, and e^-(ref). $\Delta_f H°(Hg \rightarrow Hg^+ + e^-, 298.15\ K)$ differs from a room temperature threshold energy due to inclusion of these enthalpies and to threshold effects discussed by Rosenstock *et al.*[4] $\Delta_f H°(298.15\ K)$ should be changed by −6.197 $kJ·mol^{-1}$ if it is to be used in the ion convention that excludes the enthalpy of the electron.

Heat Capacity and Entropy

The information on electronic energy levels and quantum weights, given by Moore,[2,6] is incomplete because many theoretically predicted levels have not been observed. Our calculations indicate that any reasonable method of filling in these missing levels and cutting of the summation in the partition functions[7] has no effect on the thermodynamic functions to 6000 K. This is a result of the high energy of all levels other than the ground state and the first four excited states; the next excited state is approximately 79704 cm^{-1} above the ground state. Since inclusion of these excited states has no effect on the thermodynamic functions (to 6000), we list only the ground state and the first four excited states. The reported uncertainty in $S°(298.15\ K)$ is due to uncertainties in the relative ionic mass and the fundamental constants. Extension of these calculations above 6000 K may require consideration of the excited states and use of different fill and cutoff procedures.[7]

Enthalpy of Formation

Wieland and Herczog[1] gave 8.3 ± 1.1 kcal·mol^{-1} for the enthalpy of dissociation into gaseous atoms.

Heat Capacity and Entropy

Vibrational constants were taken from Wieland.[2] Rotational constants are estimated using equation III–123 in Herzberg.[3] The bond length was estimated to be 0.965 of the mercuric bond length by analogy with the mercury chlorides.

PREVIOUS: December 1961 (1 atm) CURRENT: December 1961 (1 bar)

Mercury Iodide (HgI_2) CRYSTAL $M_r = 454.3990$

$S°(298.15\ K) = [181.326 \pm 6.3]\ J \cdot K^{-1} \cdot mol^{-1}$
$T_{trs} = 402\ K$
$T_{fus} = 530\ K$

$\Delta_f H°(298.15\ K) = -105.437 \pm 1.7\ kJ \cdot mol^{-1}$
$\Delta_{trs} H° = 2.515 \pm 0.17\ kJ \cdot mol^{-1}$
$\Delta_{fus} H° = 18.966 \pm 0.21\ kJ \cdot mol^{-1}$

Enthalpy of Formation

The value recommended by NBS[1] is adopted.

Heat Capacity and Entropy

The heat capacity is calculated from the enthalpy data of Guinchant[2] and Ewald.[3] The entropy is estimated by adjusting its value to provide the best fit of the melting, sublimation and vaporization phenomena.

Transition and Fusion Data

The enthalpy of transition, $\Delta_{trs} H° = 0.601 \pm 0.04\ kcal \cdot mol^{-1}$, and the temperature of transition are taken from NBS.[1] The enthalpy of melting, $\Delta_{fus} H° = 4.533 \pm 0.05\ kcal \cdot mol^{-1}$ was taken from Guinchant,[2] the temperature of melting from NBS.[1]

PREVIOUS: CURRENT: March 1962

$S°(298.15\ K) = [215.663]\ J·K^{-1}·mol^{-1}$
$T_{fus} = 530\ K$

$\Delta_f H°(298.15\ K) = [-87.287]\ kJ·mol^{-1}$
$\Delta_{fus} H° = 18.966 \pm 0.21\ kJ·mol^{-1}$

Enthalpy of Formation

$\Delta_f H°(HgI_2, l, 298.15\ K)$ is calculated from $\Delta_f H°(HgI_2, cr, 298.15\ K)$ by adding the enthalpy of fusion, $\Delta_{fus} H°$, and the difference in enthalpy, $H°(530\ K) H°(298.15\ K)$, between the crystal and liquid.

Heat Capacity and Entropy

Heat capacity measurements were obtained from the data of Guinchant[1] in the range 540–600 K and were assumed constant above and below this range. A glass type transition is assumed at 353 K below which the heat capacity is assumed to be that of HgI_2(cr). $S°$(l, 298.15 K) is calculated in a manner analogous to that used for the enthalpy of formation.

Fusion and Vaporization Data

$T_{vap} = 627$ K (1 atm) is taken from NBS,[2] $\Delta_{vap} H° = 14.141 \pm 0.25\ kcal·mol^{-1}$ (for $T_{vap} = 627$ K) was obtained from the data of Prideaux[3] and Johnson.[4]

Enthalpy of Formation

The enthalpy of formation of the crystal as given in National Bureau of Standards[1] was combined with the 3rd law heat of sublimation at 298.15 K derived from the data of Niwa and Shibata,[2] Magee[3] and Johnson.[4]

Heat Capacity and Entropy

The vibrational constants were given by Klemperer and Lindeman.[5] The anti-symmetric stretching frequency is estimated by analogy with the bromide and chloride. The bond length is an average of the values given by Braune and Knoke,[6] Gregg *et al.*[7] and Akishin *et al.*[8]

PREVIOUS: March 1962 (1 atm) CURRENT: March 1962 (1 bar)

$S°(298.15\ K) = 70.270 \pm 0.13\ J \cdot K^{-1} \cdot mol^{-1}$

$\Delta_f H°(0\ K) = -86.208 \pm 0.100\ kJ \cdot mol^{-1}$

$\Delta_f H°(298.15\ K) = -90.789 \pm 0.100\ kJ \cdot mol^{-1}$

Enthalpy of Formation

Calculated from the entropy obtained by Bauer and Johnston[1] and the Gibbs energy of formation as determined from the numerous cell measurements described by Bauer and Johnston. The value adopted for $\Delta_f H°(298.15\ K)$ is $-42707 \pm 14\ cal \cdot mol^{-1}$.

Heat Capacity and Entropy

The heat capacity has been measured from 15 to 298.15 K by Bauer and Johnston.[1] The extrapolation below 15 K was done assuming a T^3 law and gave $S°(15\ K) = 0.264\ cal \cdot K^{-1} \cdot mol^{-1}$. Above 298.15 the data was extrapolated smoothly and adjusted to give the observed decomposition vapor pressures of Taylor and Hulett.[2]

Decomposition Data

According to Taylor and Hulett,[2] the vapor pressure reaches 1.89 atmospheres at 749 K. This corresponds to the decomposition to 2 Hg(g) + O_2(g), the equilibrium constant being unity at 1.89 atm.

Enthalpy of Formation

The enthalpy of formation, $\Delta_f H°$(HgO, g, 298.15 K), is estimated to be 10 ± 15 kcal·mol^{-1}. This value is obtained from the enthalpy of formation of PbO(g) and comparison of the enthalpy of formation of analogous lead and mercury compounds using the method of Karapet'yants.[1] The corresponding dissociation energy, $D_0°$(HgO,g) is 64 ± 15 kcal·mol^{-1}.

Heat Capacity and Entropy

The equilibrium internuclear separation (r_e) of HgO(g) is estimated from the corresponding quantity for PbO(g) and comparison of Hg–X and Pb–X bond distances for cases in which values of both distances are known. The rotational constant B_e is calculated from r_e. The fundamental vibrational frequency ω_e is estimated from Guggenheimer's relation for multiple bonded molecules.[2] The anharmonic vibrational term $\omega_e x_e$ is calculated from $\omega_e x_e = \omega_e^2/(4D_0 + 2\ \omega_e)$. The value of α_e is calculated from the Morse potential function. The ground state configuration is estimated from the building–up principle,[3] the united atom theory,[3] and from analogy with BeO.

$S°(298.15\ K) = 241.29 \pm 8.4\ J \cdot K^{-1} \cdot mol^{-1}$
$T_{fus} = 563\ K$

$\Delta_f H°(298.15\ K) = -119.085 \pm 2.1\ kJ \cdot mol^{-1}$
$\Delta_{fus} H° = [27.196 \pm 8.4]\ kJ \cdot mol^{-1}$

Enthalpy of Formation

The average value of the cell measurements of Vosburgh,[1] Cohen,[2] Yoshida,[3] Oholm[4] and the calorimetric values of Varet[5] and Nernst[6] is adopted.

Heat Capacity and Entropy

The heat capacity at 298.15 K is taken from NBS[7] and is estimated above this by analogy with mercurous chloride. The entropy is obtained from the enthalpy and Gibbs energy of formation obtained from the cell measurements listed under enthalpy of formation.

Fusion Data

Yvon[8] gives 563 K for the melting point. The enthalpy of melting is estimated by assuming the entropy of melting per atom to be the same as that for mercuric iodide.

$S°$(298.15 K) = [273.258] J·K^{-1}·mol^{-1}
T_{fus} = 563 K

$\Delta_f H°$(298.15 K) = [−98.564] kJ·mol^{-1}
$\Delta_{fus} H°$ = [27.196 ± 8.4] kJ·mol^{-1}

Enthalpy of Formation

$\Delta_f H°(Hg_2I_2, l, 298.15\ K)$ is calculated from $\Delta_f H°(Hg_2I_2, cr, 298.15\ K)$ by adding the enthalpy of fusion, $\Delta_{fus} H°$, and the difference in enthalpy, $H°(563\ K) - H°(298.15\ K)$, between the crystal and liquid.

Heat Capacity and Entropy

$C_p°$ is estimated as 1.33 times the heat capacity of mercuric iodide. $S°$(l, 298.15 K) is calculated in a manner analogous to that used for the enthalpy of formation.

Fusion Data

The melting point was given by Yvon.[1] The enthalpy of melting was estimated from that of mercuric iodide, by assuming the entropies of melting per atom to be equal.

Vaporization Data

Mercurous iodide decomposes to Hg(g) and HgI_2(g) at the boiling point which was estimated from the Gibbs energy change of the reaction. For 1 atm, T_{vap} = [630] K (decomposition).

Enthalpy of Formation

The adopted value for the enthalpy of formation of I(g) is derived from the spectroscopically determined dissociation energy of I_2(g) as reported by Barrow *et al.*[1,2] This value is also recommended by Brewer and Winn[3] and Huber and Herzberg.[4] The adopted value is $D°_0(I_2, g)$ = 12440.06 ± 0.03 cm^{-1} (148.816 ± 0.001 $kJ·mol^{-1}$). The convergence limit in the absorption spectrum of the $^3\Pi_{0^+_u} - {}^1\Sigma_{+g}$ system corresponds to dissociation to a ground state iodine atom ($^3P_{3/2}$) and an excited state iodine atom ($^3P_{1/2}$).

Using earlier data, the CODATA recommended value[5] was calculated using $D°_0(I_2, g)$ = 12440.9 ± 1.1 cm^{-1} from LeRoy,[6] Brown,[7] LeRoy and Bernstein,[8] and Sitterley.[9] LeRoy,[6] LeRoy and Bernstein,[8] and a recent study by LeRoy and Bernstein[10] obtained the dissociation energy from the analysis of the distribution of the uppermost vibrational levels. Their calculations were based on the data of Brown,[7] with reference to the study by Verma.[11]

Heat Capacity and Entropy

Information on the electronic energy levels and quantum weights is taken from Moore.[12,13] Only two levels are included in the calculation. All other levels (observed and predicted) lie above 54633 cm^{-1}. Our calculations indicate that any reasonable method of filling in the missing levels and cutting off the summation in the partition function[14] has no effect on the thermodynamic properties to 6000 K. This is undoubtedly a result of the high energy of these levels. Therefore, we list only the ground state and the first excited state. Extension to higher temperatures may require consideration of the higher excited states and utilization of different fill and cutoff procedures.

The thermodynamic functions at 298.15 K are in agreement with recent CODATA recommendations[15] except for two minor differences. First, the entropy differs by 0.1094 $J·K^{-1}·mol^{-1}$ because this table uses a standard-state pressure of 1 bar, whereas the CODATA recommendations are based on 1 atm. Second, entropy differences of the order of 0.001–0.004 $J·K^{-1}·mol^{-1}$ for the monatomic halogens arise due to the use of slightly different values for the relative atomic mass and for R; this table uses R 8.31441 $J·K^{-1}·mol^{-1}$. Considering these minor changes, this table agrees within the estimated uncertainty with those by Hultgren *et al.*,[16] Gurvich *et al.*[17] and Wagman *et al.*[20] The estimated uncertainty is due to uncertainties in the relative atomic mass and fundamental constants which are based on the 1981 scale[18] and the 1973 values,[19] respectively.

Enthalpy of Formation

$\Delta_f H°(I^+, g, 0 K)$ is calculated from $\Delta_f H°(I, g, 0 K)$[1] using the spectroscopic value of IP(I) = 84295.1 ± 0.2 cm^{-1}(1008.39 ± 0.01 $kJ·mol^{-1}$) from Moore.[2] The ionization limit is converted from cm^{-1} to $kJ·mol^{-1}$ using the factor, 1 cm^{-1} = 0.01196266 $kJ·mol^{-1}$, which is derived from the 1973 CODATA fundamental constants.[3] Rosenstock *et al.*[4] and Levin and Lias[5] have summarized additional ionization potential and appearance potential data.

$\Delta_f H°(I^+, g, 298.15 K)$ is calculated from $\Delta_f H°(I, g, 0 K)$ by using IP(I) with JANAF[1] enthalpies, $H°(0 K)-H°(298.15 K)$, for I(g), $I^+(g)$, and e^-(ref). $\Delta_f H°(I \rightarrow I^+ + e^-, 298.15 K)$ differs from a room temperature threshold energy due to inclusion of these enthalpies and to threshold effects discussed by Rosenstock *et al.*[4] $\Delta_f H°(298.15 K)$ should be changed by −6.197 $kJ·mol^{-1}$ if it is to be used in the ion convention that excludes the enthalpy of the electron.

Heat Capacity and Entropy

The information on electronic energy levels and quantum weights, given by Moore,[2,6] is incomplete because many theoretically predicted levels have not been observed. Our calculations indicate that any reasonable method of filling in these missing levels and cutting off the summation in the partition function[7] has no effect on the thermodynamic functions to 6000 K. This is a result of the high energy of all levels other than the ground state and the lowest four excited states; the next lowest level is approximately 81040 cm^{-1} above the ground state. Since inclusion of these upper levels has no effect on the thermodynamic functions (to 6000 K), we list only the ground state and four excited states, with the energy of these states taken from recent study by Moore.[2,6] The reported uncertainty in $S°$(298.15 K) is due to uncertainties in the relative ionic mass, fundamental constants, and the position of the four lowest excited states. Extension of these calculations above 6000 K may require consideration of the higher excited states and use of different fill and cutoff procedures.[7]

Enthalpy of Formation

$\Delta_f H°(I^-, g, 0\ K)$ is calculated from $\Delta_f H°$ (I, g, 0 K)[1] using the adopted electron affinity of EA (I) = 3.0591 ± 0.0004 eV (295.156 ± 0.039 kJ·mol^{-1}). This value, recommended by Hotop and Lineberger,[6] is based on laser optogalvanic spectroscopy.[5] Additional information on I^-(g) may be obtained in the critical discussions of Hotop and Lineberger,[2,6] Rosenstock *et al.*[3] and Massey.[4]

$\Delta_f H°(I^-, g, 298.15\ K)$ is obtained from $\Delta_f H°$(I, g, 0 K) by using EA(I) with JANAF[1] enthalpies, $H°(0\ K) - H°(298.15\ K)$, for I^-(g), I(g), and e^-(ref). $\Delta_r H°(I^- \rightarrow I + e^-, 298.15\ K)$ differs from a room-temperature threshold energy due to inclusion of these enthalpies and to threshold effects discussed by Rosenstock *et al.*[3] $\Delta_f H°$(298.15 K) should be changed by + 6.197 kJ·mol^{-1} if it is to be used in the ion convention that excludes the enthalpy of the electron.

Heat Capacity and Entropy

The ground state configuration for I^-(g) is given by Hotop and Lineberger,[2,6] Rosenstock *et al.*[3] and Massey.[4] Lacking any experimental evidence as to the stability of any excited states, we assume that no stable excited states exist.

The entropy at all temperatures (0–6000 K) agrees within 0.001 J·K^{-1}·mol^{-1} with the values of Gurvich *et al.*[8] except for one minor difference. The entropy differs by 0.1094 J·K^{-1}·mol^{-1} because this table uses a standard-state pressure of 1 bar, whereas the tabulation of Gurvich, *et al.*[8] is based on 1 atm. The estimated uncertainty is due to uncertainties in the relative ionic mass and the fundamental constants which are based on the 1981 scale[9] and the 1973 values,[7] respectively.

PREVIOUS: CURRENT: June 1982 (1 bar)

$S°(298.15\ K) = 106.387\ J·K^{-1}·mol^{-1}$
$T_{fus} = 954\ K$

$\Delta_f H°(0\ K) = -326.93 \pm 0.4\ kJ·mol^{-1}$
$\Delta_f H°(298.15\ K) = -327.90 \pm 0.4\ kJ·mol^{-1}$
$\Delta_{fus} H° = 24.016\ kJ·mol^{-1}$

Enthalpy of Formation

The enthalpies of solution of KI(cr) have been critically reviewed by Parker.[1] Six pertinent results are quoted in the table below. Adopting the best value, $\Delta_\infty H°(298.15\ K) = 4.86 \pm 0.03\ kcal·mol^{-1}$, reported by Parker, and $\Delta_f H°(298.15\ K) = -60.32$ and $-13.19\ kcal·mol^{-1}$ for K^+(aq, ∞) and I (aq, ∞), respectively, obtained from,[2] we obtain $\Delta_f H°$(KI, cr, 298.15 K) = $-78.37 \pm 0.1\ kcal·mol^{-1}$, which is adopted.

$\Delta_f H°$, kcal·mol^{-1}(a)	T/°C	n(b)	Source
4.830 ± 0.05	19	200	Thomsen[3]
4.897 ± 0.04	25	18	Wust and Lange[4]
4.873	25	500	Lange and Martin[5]
4.790 ± 0.10	20.5	600	Popov *et al.*[6]
5.020	24.5	18.5	Bobtelsky and Lairsch[7]
4.830 ± 0.07	25	75000	Kapustinskii and Drakin[8]

a Values are adjusted to 298.15 K and to infinite dilution.
b n is the number of moles of H_2O per mole of KI(cr) in solution.

Heat Capacity and Entropy

The low temperature heat capacities are based on those measured by Berg and Morrison,[9] 2.86–268.0 K. The adopted values are in good agreement with the $C_p°$ values reported by Scales,[10] 2–7 K. The data of Clusius *et al.*,[11] 10.27–269.9 K, appear to be too low in the temperature range 70–270 K and are not used. Low temperature enthalpies, 83–273 K, have been measured by Koref.[12] The value of $S°(298.15\ K)$ is derived based on the adopted low temperature heat capacities, using $S°(2.86\ K) = 0.0033\ cal·K^{-1}·mol^{-1}$.

The high temperature enthalpies were determined by Skuratov and Lapushkin,[13] 623–923 K; Dworkin,[14] 854–954 K; and Cooper,[15] 297–973 K. Heat capacities are derived from the enthalpies by a curve fitting method which requires a smooth joint with the low temperature $C_p°$. Enthalpy values used in the curve fit include smooth values calculated from the equation of Skuratov and the value $H°(954)-H°(298.15) = 9.2\ kcal·mol^{-1}$ from Dworkin. Deviation of the input values from the selected enthalpies are all less than 0.3 percent, while the deviations of the data of Cooper range from +1.0 at 570 K to −1.6 percent at 974 K. Since the latter point is 20 above the melting point, there appears to be an error in Cooper's measurement of temperature. $C_p°$ above the melting point is obtained by graphical extrapolation.

Fusion Data

T_{fus} has been reported to be 953, 952, and 954 K by Ray and Dayal,[16] Phipps and Partridge,[17] and Johnson and Bredig,[18] respectively. The latter value is adopted. The enthalpy of fusion was determined by Dworkin and Bredig,[19] using drop calorimetry

Sublimation Data

The difference between $\Delta_f H°(298.15\ K)$ for KI(g) and KI(cr) is $\Delta_{sub} H°$(to monomer, 298.15 K). The $\Delta_{sub} H°$(to dimer, 298.15 K K) is calculated as the enthalpy change for the following reaction: $2KI(cr) = K_2I_2(g)$.

$S°(298.15\ K) = [114.098]\ J·K^{-1}·mol^{-1}$
$T_{fus} = 954\ K$

$\Delta_f H°(298.15\ K) = [-312.846]\ kJ·mol^{-1}$
$\Delta_{fus}H° = 24.016\ kJ·mol^{-1}$

Enthalpy of Formation

$\Delta_f H°$(KI, l, 298.15 K), is calculated from $\Delta_f H°$(KI, cr, 298.15 K) by adding the enthalpy of fusion, $\Delta_{fus}H°$, and the difference in enthalpy, $H°(954\ K) - H°(298.15\ K)$, between the crystal and liquid.

Heat Capacity and Entropy

The heat capacity is derived as 17.3 cal $K^{-1}·mol^{-1}$ from the enthalpy measurements, 954–1014K, by Dworkin.[1] This $C_p°$ value is adopted in the temperature range 298.15 K. $S°$(298.15 K) is calculated in a manner analogous to that used for the enthalpy of formation.

Fusion Data

Refer to the crystal table for details.

Vaporization Data

The boiling point, T_{vap} = 1618 K (1 atm), is calculated as the temperature at which the sum of the partial pressure of KI(g) and K_2I_2(g) over KI(l) equals one atmosphere. The value of $\Delta_{vap}H°$ is calculated as the heat required to produce one mole of vapor mixture, which contains 78 percent monomer (KI) and 22 percent dimer (K_2I_2) at T_{vap}.

T_{vap} was reported as 1603 and 1590 K by Wartenberg and Albrecht,[2] and Ruff and Mugdan,[3] respectively.

Enthalpy of Formation

The enthalpy of formation is derived from the sublimation and vaporization data analyzed below. Many investigators have determined the total pressures of KI(g) and K_2I_2(g) over KI(cr) or KI(l) by static methods or "apparent" pressures by Knudsen effusion or transpiration. These pressures are converted to monomer pressures by use of functions [refer to K_2I_2(g) table] which are consistent with the dimer monomer equilibrium data of Datz.[9] 2nd and 3rd law analyses of the monomer pressures show reasonable agreement. The selected value of $\Delta_f H°(298.15\ K) = -30.0 \pm 0.5\ kcal·mol^{-1}$ is also in good agreement with -30.23 ± 1.15 and $-30.46\ kcal·mol^{-1}$ derived from $D_0° = 3.32 \pm 0.05$ and 3.33 eV reported by Gaydon[10] and Herzberg[11] respectively.

*Reactions: (A) KI(cr) = KI(g); (B) KI(l) = KI(g).

Heat Capacity and Entropy

The ground state configuration is obtained from Herzberg.[11] The adopted values of ω_e, $\omega_e x_e$, B_e, α_e, and r_e were determined using millimeter wave molecular beam spectroscopy by Rusk and Gordy[12] and corrected to the average isotopic species. Similar values were reported by Honig *et al.*[13] from microwave spectra, except ω_e which was given as 199.74 cm^{-1}. The value of ω_e was derived to be 200 and 173 cm^{-1} by Barrow and Caunt[14] and Rice and Klemperer.[15] The moment of inertia is 4.5979×10^{-38} g cm^2.

PREVIOUS: June 1967 (1 atm) CURRENT: June 1967 (1 bar)

$S°(298.15\ K) = [85.772]\ J·K^{-1}·mol^{-1}$
$T_{fus} = 742\ K$

$\Delta_f H°(0\ K)$ = Unknown
$\Delta_f H°(298.15\ K) = -270.08 \pm 0.4\ kJ·mol^{-1}$
$\Delta_{fus} H° = 14.644\ kJ·mol^{-1}$

Enthalpy of Formation

The enthalpy of formation. $\Delta_f H°$(LiI, cr, 298.15 K) = −64.55 kcal·mol^{-1}, was calculated from the heat of solution of lithium iodide (cr) at infinite dilution and the ionic heats of formation of Li^+(aq,∞) and I^-(aq,∞).

Parker[1] reviewed the literature heat of solution data and gave the "best" value, $\Delta_{sol} H°$(aq,linfl) = −15.130 ± 75 cal·K^{-1}·mol^{-1} for LiI(cr) → LiI(aq,linfl) at 298.15 K. The ionic heat of formation, $\Delta_f H°(Li^+, aq, ∞, 298.15\ K)$ = −66.49 kcal·mol^{-1} was calculated from $\Delta H°$(LiOH·aq, ∞, 298.15 K) = −121.46 kcal·mol^{-1} (see JANAF LiOH(cr) table, Mar. 31, 1966) with $\Delta_f H°(OH^-\cdot aq, ∞, 298.15\ K)$ = −54.97 kcal·mol^{-1} from.[2] The value $\Delta_f H°(I^-\cdot aq, ∞, 298.15\ K)$ = 13.19 kcal·mol^{-1} was also obtained from[2] Combination of the ionic heats of formation of Li^+(aq, ∞) and I^- (aq, ∞) gives the heat of formation of LiI(aq, ∞), $\Delta_f H°$(298.15 K) = −79.68 kcal·mol^{-1}.

Heat Capacity and Entropy

Dworkin[3] has measured the enthalpy changes by the drop method (642–802 K), yielding $H°(742\ K) - H°(298.15\ K)$ = 6.0 kcal·mol^{-1} for the crystal at the melting point. Heat capacities derived from his data were $C_p°(692\ K)$ = 14.8 and $C_p°(772\ K)$ = 15.1 cal·K^{-1}mol^{-1} for the crystal and liquid, respectively. The tabulated heat capacities were estimated based on these values and on the heat capacities of LiCl(cr), NaCl(cr) and NaI(cr).

The entropy, $S°(298.15\ K)$ = 20.5 cal·K^{-1}·mol^{-1}, was estimated by adding the entropy difference at 298.15 K between NaI(cr) and NaCl(cr) to the entropy of LiCl(cr). Comparisons with other alkali halides give results within ±0.5 cal·K^{-1}·mol^{-1} of this value.

Kelley[4] has estimated the heat capacities ($C_p° = 12.30 + 2.44 \times 10^{-3} T$ cal·K^{-1}·mol^{-1}) and the entropy, $S°(298.15\ K)$ = 17.50 cal·K^{-1}·mol^{-1}.

Fusion Data

The selected enthalpy of fusion, $\Delta H°(823\ K)$ = 350 kcal·mol^{-1}) was obtained from enthalpy measurements in a drop calorimeter by Dworkin and Bredig.[5]

PREVIOUS: September 1961 CURRENT: June 1966

$S°(298.15\ K) = [98.611]\ J·K^{-1}·mol^{-1}$
$T_{fus} = 742\ K$

$\Delta_f H°(298.15\ K) = [-258.349]\ kJ·mol^{-1}$
$\Delta_{fus}H° = 14.644\ kJ·mol^{-1}$

Enthalpy of Formation

$\Delta_f H°$(LiI, l, 298.15 K) is calculated from $\Delta_f H°$(LiI, cr, 298.15 K) by adding the enthalpy of fusion, $\Delta_{fus}H°$, and the difference in enthalpy, $H°(742\ K) - H°(298.15\ K)$, between the crystal and liquid.

Heat Capacity and Entropy

Dworkin[1] has derived the heat capacity ($C_p°$ = 15.1 $cal·K^{-1}·mol^{-1}$) from enthalpy measurements (742–802 K) by the drop method. The liquid heat capacity was assumed to be constant as 15.1 $cal·K^{-1}·mol^{-1}$. The entropy at 298.15 K is calculated in a manner analogous to that used for the enthalpy of formation.

Fusion Data

Refer to the crystal table for details.

Vaporization Data

T_{vap}(to monomer only) = 1497 K is determined as the temperature at which the fugacity is 1 atm for the reaction LiI(l) = LiI(g). The corresponding enthalpy change ($\Delta_r H°$) at boiling point is the enthalpy of vaporization $\Delta_{vap}H°$(to monomer only).

T_{vap}(to equilibrium mixture) = 1447 K is the temperature at which the sum of the calculated partial vapor pressures of LiI(g) and Li_2I_2(g) reaches one atmosphere (trimer and higher polymer have been neglected in calculation). This value is in good agreement with the boiling point of 1444 K from the least squares fit of the total vapor pressure data measured by Ruff and Mugdan.[2] $\Delta_{vap}H°$(to equilibrium mixture) at the boiling point is calculated as the heat of vaporization of one mole of liquid to vapor containing 30.44 mole percent of dimer. For detailed information see LiI(g) and Li_2I_2(g) tables.

Enthalpy of Formation

The enthalpy of formation, $\Delta_f H°$(LiI, g, 298.15 K) = −21.75 ± 2 kcal·mol^{-1}, was calculated from the selected heat of sublimation and the enthalpy of formation for lithium iodide (cr). The heat of sublimation has been determined mass spectrometrically from the ion intensity measurement (2nd law method) by Gorokhov as $\Delta_{sub}H°$(cr → monomer, 298.15 K) = 42.9 ± 0.6 and $\Delta_{sub}H°$(cr → dimer, 298.15 K) = 43.2 ± 0.4 kcal·mol^{-1} in the temperature range from 626–722 K. Gorokhov also reported the partial vapor pressure of monomeric lithium iodide ($P_{monomer} = 3 \times 10^{3}$ mm Hg) and the ratio of dimer to monomer ($P_{dimer}/P_{monomer} = 6$) which have been used for 3rd law calculation. Using the same technique, Friedman reported the heats of sublimation as $\Delta_{sub}H°$(cr → monomer, 727 K) = 41.9 ± 0.5 and $\Delta_{sub}H°$(cr → dimer, 727 K) = 40.8 ± 0.5 kcal·mol^{-1} in the temperature range from 630 to 730 K. Berkowitz *et al.* have also studied the lithium iodide vapor in the mass spectrometer and reported the 2nd law and 3rd law values of the heat of dimerization at 800 K as 37.9 and 40.4 kcal·mol^{-1}, respectively. Using the JANAF thermodynamic functions, all the heats of sublimation and dimerization at different temperatures have been reduced to 298.15 K and summarized in the following table. The total vapor pressure over the liquid has been measured by a boiling point method in the temperature range 1223 to 1413 K by Ruff and Mugdan[4] (Their data have been quoted by Wartenberg and Schulz.)[5] In order to have good agreement between the calculated vapor pressure and the observed total vapor pressure, the heats of sublimation have been so chosen as $\Delta_{sub}H°(298.15\ K) = 42.8$ kcal·mol^{-1} and $\Delta_{sub}H°$(cr → dimer, 298.15 K) = 42.6 kcal·mol^{-1} and the heat of dissociation of dimer, $\Delta_d H°$(cr → monomer, 298.15 K) = 43.0 kcal·mol^{-1}. The calculated boiling point (to equilibrium mixture) is 1449 K which agrees with 1443 K reported by Wartenberg and Schulz, and also 1462 K by Ruff and Mugdan.

Reaction	Source	$\Delta_r H°(298.15\ K)$, kcal·mol^{-1} 2nd law	3rd law
LiI(cr) → LiI(g)	Gorokhov	44.7	42.2
	Friedman	43.9	–
2 LiI(cr) → Li_2I_2(g)	Gorokhov	46.0	41.3
	Friedman	44.1	–
Li_2I_2(g) → 2 LiI(g)	Berkowitz *et al.*	38.8	41.3
	Friedman	43.7	–
	Gorokov	43.2	43.1

Heat Capacity and Entropy

The bond distance and the rotational constants (B_e and ν_e), corrected to the isotopic abundance of 7.4% Li^6 and 92.6% Li^7 were obtained from the microwave studies by Honig *et al.*[6] The vibrational constants (ω_e and $\omega_e x_e$) were determined from the infrared spectrum by Klemperer *et al.*[7]

The tabulated thermodynamic functions are in reasonable agreement with those calculated by Wilkins who used slightly different molecular constants.

$A[^2\Pi]$	24319	2
	25294	2

$\omega_e = 312\ cm^{-1}$ $\omega_e x_e = [1.09]\ cm^{-1}$ $\sigma = 1$

$B_e = [0.13014]\ cm^{-1}$ $\alpha_e = [0.00062]\ cm^{-1}$ $r_e = [2.52]$ Å

Enthalpy of Formation

The adopted $\Delta_f H°(0\ K) = 6.309 \pm 10\ kcal·mol^{-1}$ is calculated from a $D_0°$ value of 54.3 $kcal·mol^{-1}$ (2.35 $cal·K^{-1}·mol^{-1}$). An approximate value of 312 cm^{-1} has been given for ω_e.[1] A value of $\omega_e x_e$, 1.09 cm^{-1}, is calculated from an average value of $x_e\mu^{1/2}$ calculated from data for CaI, SrI, BaI, MgBr, and MgCl.[1,2] A linear Birge–Sponer extrapolation of these ω_e and $\omega_e x_e$data is corrected for the ionic character of the molecule as described by Hildenbrand to give the adopted value of $D_0° = 54.3\ kcal·mol^{-1}$.

From a consideration of ionic bonding forces, Krasnov and Karaseva[4] calculated $D_0° \geq 55 \pm 10\ kcal·mol^{-1}$.

Using JANAF data, $D_0°(MgI)$ $D_0°(MgI_2) = 0.44$, in reasonable agreement with the ratios found by Blue *et. al.*[5] for the alkali earth fluorides and by Hildenbrand for the alkaline with fluorides and chlorides.

$\Delta_f H°(298.15\ K) = 5.883 \pm 10\ kcal·mol^{-1}$ is calculated from the adopted $\Delta_f H°(0\ K) = 6.309\ kcal·mol^{-1}$.

Heat Capacity and Entropy

The ground state vibrational constants are as given in the Enthalpy of Formation section above. The adopted value of $r_e = 2.52$ Å is the bond distance in MgI_2.[7] Margrave[8] has estimated 2.72 Å from additive ionic radii. B_e is calculated from the adopted r_e, and α_e is calculated assuming a Morse potential function.

The electronic levels and their designation are those given by Rosen.[1] The possibility of additional electronic levels near 15000 cm^{-1} is suggested by a comparison with CaI, SrI, and BaI.[2] Including these levels does not change the entropy at 298.15 K and increases the entropy at 6000 K by only 0.69 $cal·K^{-1}·mol^{-1}$.

Enthalpy of Formation

The adopted value of $\Delta_f H°$ at 298.15 K is that estimated by Brewer.[1] The estimated value is consistent with the low volatility of solid molybdenum in iodine vapor reported by Schafer *et al.*[2] Brewer's estimated value is given as $\Delta_f H°(298.15\ K)/R = 60000 \pm 5000$. The assigned uncertainty ($\pm 10\ kcal·mol^{-1}$) is determined from the product $500 \times R$ which has been rounded to the nearest $kcal·mol^{-1}$. The value of $\Delta_f H°(0\ K)$ combined with JANAF data[3] for Mo(g) and I(g) gives $D_0°(Mo–I) = 63 \pm 11\ kcal·mol^{-1}$.

Heat Capacity and Entropy

We use values of r_e and ω_e estimated by Brewer.[1] The electronic contribution is taken to be the same as that for the free gaseous Mo^+ ion, as suggested by Brewer.[1] The levels listed by Moore[4] below 17334 cm^{-1} are used in the calculations. Our thermodynamic functions differ slightly from those reported by Brewer[1] due to the use of non–zero values for $\omega_e x_e$ and α_e. Estimates for α_e and ω_e are based on the empirical correlations of Calder and Ruedenberg.[5]

Ground State Quantum Weight: 1 $\alpha = 1$

Point Group: C_s

Bond Distances: O–N = [1.15] Å N–I = [2.3] Å

Bond Angle: O–N–I = [120]°

Product of the Moments of Inertia: $I_A I_B I_C = [7.908120 \times 10^{-115}]\ g^3·cm^6$

Enthalpy of Formation

The enthalpy of formation $\Delta_f H°(298.15\ K)$ for INO(g) is estimated by comparison with those for FNO(g), ClNO(g), BrNO(g), and the related cyanogen halides.

Heat Capacity and Entropy

The molecular structure and bond angle are estimated by comparison with those for ClNO(g) and BrNO(g). The N–O bond distance is assumed to be the same as that in NO(g). The N–I bond distance, r(N–I) is calculated based on an assumption that r(ON–Cl) r(ON–I) = r(I–Cl r(I–I). The vibrational frequencies are estimated by comparison with those for FNO(g), ClNO(g) and BrNO(g). The three principal moments of inertia are: $I_A = 0.8962 \times 10^{-39}$, $I_B = 29.2605 \times 10^{-39}$, and $I = 30.1568 \times 10^{-39}$ g·cm^2.

PREVIOUS: December 1966 (1 atm) CURRENT: December 1966 (1 bar)

$S°(298.15\ K) = 98.500\ J·K^{-1}·mol^{-1}$
$T_{fus} = 933\ K$

$\Delta_f H°(0\ K) = -287.34 \pm 0.8\ kJ·mol^{-1}$
$\Delta_f H°(298.15\ K) = -287.86 \pm 0.8\ kJ·mol^{-1}$
$\Delta_{fus} H° = 23.598\ kJ·mol^{-1}$

Enthalpy of Formation

The enthalpy of formation was obtained as follows:

	$\Delta_f H°$(298.15 K) kcal·mol^{-1}
(1) $HI·100H_2O + NaOH·100H_2O \rightarrow NaI·201H_2O$	-13.51 ± 0.02[1]
(2) $Na(cr) + 1001H_2O(l) \rightarrow NaOH·1000H_2O + 1/2H_2(g)$	-44.069 ± 0.006[2]
(3) $NaOH·1000H_2O \rightarrow NaOH·100H_2O + 900H_2O(l)$	$+0.031 \pm 0.004$[3]
(4) $1/2H_2(g) + 1/2I_2(s) \rightarrow HI(g)$	$+6.30 \pm 0.05$[4]
(5) $HI(g) + 100H_2O(l) \rightarrow HI·100H_2O$	19.30 ± 0.05[5]
(6) $NaI·201H_2O(l) \rightarrow NaI(cr) + 201\ H_2O(\ell)$	$+1.75 \pm 0.06$[6,7,8]
(1) + (2) + (3) + (4) + (5) + (6) gives $Na(cr) + 1/2I_2(s) \rightarrow NaI(cr)$	-68.80 ± 0.2

Heat Capacity and Entropy

Smoothed heat capacities between 3 and 270 K have been presented by Berg and Morrison.[9] Above 270 K the heat capacity was obtained by comparing with KI(cr) on a reduced temperature plot of C_p/T versus T. The values so obtained were increased by 1.4% to bring them into line with the low temperature data.

Fusion Data

Dworkin and Bredig[10] have measured both T_{fus} and $\Delta_{fus}H$.

PREVIOUS: CURRENT: September 1963

$S°(298.15\ K) = [120.754]\ J·K^{-1}·mol^{-1}$
$T_{fus} = 933\ K$

$\Delta_f H°(298.15\ K) = [-266.508]\ kJ·mol^{-1}$
$\Delta_{fus} H° = 23.598\ kJ·mol^{-1}$

Enthalpy of Formation

$\Delta H°$(NaI, l, 298.15 K) is calculated from that of the crystal by adding $\Delta_{fus} H°$ and the difference in enthalpy, $H°(933\ K) - H°(298.15\ K)$, between the crystal and liquid.

Heat Capacity and Entropy

$C_p°$ is estimated assuming each atom contributed 7.75 $cal·K^{-1}·mol^{-1}$. $S°$(NaI, l, 298.15 K) is calculated in a manner similar to that used for the enthalpy of formation.

Fusion Data

Refer to the crystal table for details.

Vaporization Data

The boiling point, T_{vap} = 1577 K (l → equilibrium mixture, 1 atm), is that given by Kelley[1] from examination of the high temperature vapor pressure.

Enthalpy of Formation

The dissociation energy has been calculated by many different techniques. The derived values range from 176 to 250 kJ·mol^{-1}. The values may be grouped into two types: (1) derived from a treatment of the observed vibrational energy levels and (2) extracted from kinetic studies.

The two existing spectroscopic studies by Coleman *et al.*[1] and Durie and Ramsay[2] yield dissociation energy values for IO(g). One should note that the first bound excited state $A^2\Pi$ of IO(g) dissociates into $I(^2P_{3/2}) + O(^1D_2)$. Coleman *et al.*,[1] from their study of the IO spectrum in flames, used a graphical Birge–Sponer technique to give 1.92 ± 0.2 eV (185 ± 19 kJ·mol^{-1}). Durie and Ramsay[2] stated that since only six bands were observed in their study of the absorption spectrum of IO, it was not possible to obtain an accurate value for the dissociation of the ground state. They derived an upper limit of <21976 cm^{-1} (2.72 eV or 262.9 kJ·mol^{-1}) from the observed predissociation. Durie and Ramsay felt that a better estimate could be obtained from a Birge–Sponer extrapolation of the first four vibrational levels in the upper state leading to D_0° = 10200 cm^{-1} for the excited state. However, since the accepted values (at that time, 1958) for ClO and BrO were approximately 10% less than the values calculated by the same procedure, they applied the same correction to IO and calculated 14800 ± 1800 cm^{-1} (1.8 ± 0.2 eV or 175.7 ± 21 kJ·mol^{-1}).

Using flame photometry, Phillips and Sugden[3] measured the intensity of the (0,4) band of IO at 5307 to determine the temperature dependent (1900–2700 K) equilibrium constant for the dissociation energy of IO and obtained D_0° = 238.5 ± 25 kJ·mol^{-1}. This value was calculated from the assumed enthalpy of formation value (relative to the monoatomic gases) of 263.6 kJ·mol^{-1} at 2000 K and is considerably higher than the earlier determined spectroscopic values. Using current thermal functions and auxiliary data we calculate D_0° = 256 kJ·mol^{-1} or 21400 cm^{-1}.

Herron and Huie[4] and Huie and Laszlo,[5] in their kinetic studies, questioned the validity of these spectroscopically derived dissociation energy values. The value from the Durie and Ramsay study is too small to be consistent with the kinetic studies. Herron and Huie preferred the results of Phillips and Sugden. Huie and Laszlo adopted an enthalpy of formation based on the molecular beam studies of Radlein *et al.*,[6] D_0° = 222 ± 13 kJ·mol^{-1}, and Buss *et al.*,[7] D_0° = 230 ± 8 kJ·mol^{-1}. Ruscic and Berkowitz,[8] in determining experimentally the ethalpy of formation and ionization potential of HOBr, inferred a new value for the enthalpy of formation of IO; $\Delta_f H^\circ$(IO, 0 K) = 145 kJ·mol^{-1}. This value was a mean of the Radlein *et al.*[6] and the spectroscopic results.[1,2] In concurrence with the arguments of Huie, Herron and Laszlo we adopt D_0° = 226 kJ·mol^{-1} which leads to $\Delta_f H^\circ$(0 K) = 128 ± 18 kJ·mol^{-1}. Additional data needed for the calculations presented here, e.g. thermal functions for I(g), and I_2(ref), O(g), and O_2(ref), are taken from JANAF Thermochemical Tables.[9] A recent photoionization study[10] confirms our adopted value.

Heat Capacity and Entropy

The spectroscopic results tabulated above are for the $^{127}I^{16}O$ isotopomer. Isotopic relationships[11] are used to convert the above constants to those natural abundance species. The latter values are then used in the calculation of the thermal functions. Only the X and A states are included in the calculation; a sum–over–states technique is used. Values of ω_e and $\omega_e x_e$ are from Bekooy *et al.*[12] and Gilles *et al.*,[13] but the value of D_e for the excited state is estimated.[11] The dissociation energy of the A state is estimated to be 12900 cm^{-1}.

The electronic ground state configuration, $X^2\Pi_{3/2}$ (inverted doublet) was confirmed by the EPR measurements of Carrington *et al.*[14] An earlier EPR spectra result, 2330 cm^{-1}, was reported by Brown *et al.*[16] The recent measured value of Gilles *et al.*,[13] 2091 cm^{-1}, for the spin–orbit splitting of the ground state is adopted here. For ClO the spin–orbit splitting of the A state was estimated to be 1.5 times the value found for the ground state.[17] Using the same factor of 1.5 the spin–orbit splitting for the A state in IO is estimated to be 3140 cm^{-1}. The position of the first excited state, $A^2\Pi_{3/2}$, was provided by Bekooy *et al.*,[12] Loewenschuss *et al.*,[18] Vaidya[19] and Durie *et al.*[20] We adopt the 21557.81 cm^{-1} value of Durie *et al.* Additional excited states have been mentioned by Callear and Metcalf[21] and Saito.[15] The higher states were not included in the thermal function calculations.

Point Group: C_{2v} σ = 2
Bond Distance: I–O = [1.8]Å
Bond Angle: O–I–O = [120]°
Product of the Moments of Inertia: $I_AI_BI_C$ = 725.5989 × 10^{-117} g^3·cm^6

Enthalpy of Formation

For the series OXO(g) [where X = F, Cl, Br, I], there are only reliable experimental data for OClO(g). Assuming that the values $D_0°$(ClO) and $\Delta_{at}H°$(OClO,g) are reasonable, we adopt the ratio of the numbers (~1.94) to apply for a similar relationship between IO(g) and OIO(g). Thus, $\Delta_{at}H°$(OIO,g, 0 K) = 1.94 $D_0°$(IO) = 438 kJ·mol^{-1}.

Heat Capacity and Entropy

Based on the ESR study by Byberg,[1] the ground state of the free IO_2 molecule belongs to the representation B_1 of the point group C_{2v}. This symmetric, bent molecule is estimated to have an O–I–O angle of [120]° and a bond length of [1.8] Å in analogy with the corresponding fluorine, chlorine, and bromine oxide molecules.[2] The principal moments of inertia in g·cm^2 are: I_A = 3.4373 × 10^{-39}, I_B = 12.1991 × 10^{-39}, and I_C = 16.3491 × 10^{-39}.

Two of the three vibrational frequencies have been derived by Gilles *et al.*[3] who used photoelectron spectroscopic techniques. ν_3 is estimated based on anticipated trends with the OXO(g) family[2] and assuming $\nu_3 > \nu_1$.

Bond Angle: I–O–O = [120]°
Product of the Moments of Inertia: $I_A I_B I_C = [1314.2931 \times 10^{-117}]\ g^3{\cdot}cm^6$

Enthalpy of Formation

Following trends[1] in the reaction XOO(g) → X(g) + 2O(g), a reasonable estimate for the iodine reaction would be 470 kJ·mol which yields $\Delta_f H°(0\ K) = -91.25\ kJ{\cdot}mol^{-1}$. However, looking at the trends in the reaction XOO(g) → XO(g) + O(g), a reasonable estimate for the iodine reaction would be 260 $kJ{\cdot}mol^{-1}$ which leads to a $\Delta_f H°(0\ K) = 119\ kJ{\cdot}mol^{-1}$. This large discrepancy in estimates is a result of the estimates and uncertainties in all XOO enthalpies of formation. We adopt the value based on the reaction involving an X–O bond breakage.

Heat Capacity and Entropy

The vibrational frequencies and structure are estimated based on the existing data for FOO(g), ClOO(g), and BrOO(g).[1] The principal moments of inertia in $g{\cdot}cm^2$ are: $I_A = 1.1391 \times 10^{-39}$, $I_B = 33.4021 \times 10^{-39}$, and $I_C = 34.5412 \times 10^{-39}$.

Enthalpy of Formation

We adopt an enthalpy of formation value which is based on an assumed relationship of $\Delta_{at}H°(IO_3,g)/3 = 0.9D°_0(IO)$.

An enthalpy of formation value has been reported by Farkas and Klein.[1] This value, − 28 kcal·mol^{-1} (−117 kJ·mol^{-1}), is derived from absorption spectra measurements of iodate ions in solutions. There is considerable uncertainty in this value, both in terms of the experimental measurements and the fact that the authors have interchanged IO_3 and IO_3^-. This corresponds to an average bond energy of 241.9 kJ·mol^{-1}. Since this value is greater than $D°_0(IO)$, it is suspect.

Heat Capacity and Entropy

The structure of this molecule is estimated to be pyramidal with a O–I–O angle of [89]° and a bond length of 1.79Å in analogy with the corresponding chlorine and bromine oxide molecules. Venkateswarlu and Sundaram,[2] Venkateswarlu and Rajalakshmi,[3] Rao and Santhamma,[4] Rao,[5] and Thirugnanasambandam and Mohan[6] assumed the same structure and bond angle for ClO_3, BrO_3 and IO_3. Using Badger's rule, the authors examined the relationship between the vibrational frequencies and force constants for the three pyramidal molecules $-ClO_3$, BrO_3, and IO_3. Although these authors refer to early measurements of the vibrational frequencies, the values appear to be in part those of the ion IO_3^-. Their reported values are adopted here although we treat them as estimated values. The vibrational frequencies are derived from the force constants which describe the other halogen oxide molecules. The principal moments of inertia in g·cm^2 are: $I_A = 14.7650 \times 10^{-39}$, $I_B = 14.7650 \times 10^{-39}$, and $I_C = 16.7280 \times 10^{-39}$.
